Many practitioners, both ancient and modern, have therefore disused and condemned it; and have, in cases where there have been no immediate bad symptoms, advised to leave the fracture to nature, and not to perform the operation as a preventative, but to wait until its necessity may be indicated by such symptoms as may both require and vindicate it. This is a point of the utmost consequence in practice, and ought to be very maturely considered.

They who object to the early use of the trephine, speak of it as being frequently unnecessary, and as rendering the patient liable to several inconveniences which may arise from uncovering the dura mater before there is any good or at least any apparent reason for so doing. And in support of this their opinion, they allege many instances of simple fracture, which have been long undiscovered, without being attended with any bad symptoms; and of others which, though known and attended to from the first, have done very well without such operation.

They who advise the immediate use of the instrument, do it upon a presumption that, in considerable violence received by the head, such mischief is done to the dura mater, and the vessels by which it is connected to the cranium, that inflammation of the said membrane must follow; which inflammation generally produces a collection of matter and a symptomatic fever, which most frequently baffles all our art, and ends in the destruction of the patient.

What the former assert is undoubtedly sometimes true. There have been several instances of undepressed fractures of the skull, which either from having been undiscovered at first, or neglected, or having been under the care of a practitioner who has disliked the operation, have done very well without it. This is certainly true, but is not sufficient to found a general rule of practice upon: in matters of this sort, a few instances are by no means sufficient to establish a precedent: that which is found to be most frequently useful, is what we ought to abide by; referring to ourselves a liberty of deviating from such general rule in particular cases.

This is one of those perplexing circumstances which all writers lament, and all practitioners feel; but which, instead of merely complaining of, we should endeavour, as much as in us lies, to correct.

In order to obtain what information we can on this subject, we should consider, first, what the mischiefs are

149
Objections to the early use of the trephine.

150
Answered.

Theory.

are, which may most probably be expected to follow, or which most frequently do follow, when perforation has been too long deferred or totally neglected; secondly, what prejudice or inconvenience does really arise from, or is thought to be caused by, the operation itself, considered abstractedly; and, thirdly, what proportion the number of those who have done well without it bears to that of those who may truly be said to have been lost for want of it, or of those to whom it might have afforded some chance of relief.

151
Dangers
arising from
a delay of
the operation.

With regard to the first, we have already observed in the case of simple undressed fractures, whenever the trephine is applied, it must be with design either to relieve or to prevent ills arising from other mischief than the mere breach in the bone; which breach, considered simply and abstractedly, can neither cause such ills, nor be relieved by such operation. One, and that the most frequent, of these mischiefs, is the inflammation, detachment, and suppuration of the dura mater, and consequently the collection of matter between it and the skull; a case of all others attending wounds of the head, the most pressing, the most hazardous, and the least within our power to relieve. Indeed, the only probable method of preventing this evil seems to be the removal of such a part of the skull as, by being broken, appears plainly to have been the part where the violence was inflicted; and which, if the dura mater becomes inflamed, and quitting its connexion suppurates, will, in all probability, cover and confine a collection of matter for which nature has provided no outlet.

152
Those
which follow
the operation
itself.

The second consideration proposed was, What mischief or inconvenience may most reasonably be supposed to follow or to proceed from the mere operation considered abstractedly. They who are averse to the use of it as a preventative, allege that it occasions a great loss of time; that it is frequently quite unnecessary; and that the admission of air to the dura mater, as well as the laying of it bare, is necessarily prejudicial.

The former of these is undoubtedly true: a person whose skull has been perforated cannot possibly be well (that is, cured) in so short a space of time as one who has not undergone such operation, supposing such person to have sustained no other injury than the mere fracture; and if the majority of the people whose skulls are broken, were so lucky as to sustain no other injury, that is, if no other mischief was in these cases in general done to the parts contained within the skull, the objection to perforation would be real and great, and the operation a matter of more serious consideration. But this is seldom the case; by much the larger number of those who suffer a fracture of the skull, are injured with regard to other parts, and labour under mischief of another kind additional to the fracture; that is, the parts within the cranium are injured as well as the cranium itself. This being the case, the loss or waste of a little time ceases to be an object of so great importance. The hazard which it is supposed may be incurred from laying bare the dura mater is indeed a matter of some weight: so that it certainly ought not to be done but for very good reasons: and yet, let the supposed hazard be what it may, it cannot, in the nature of things, be by any means equal to that which must be incurred by not doing it

when such operation becomes necessary. In short, if we would form a right judgment of this point, the question concerning it ought to stand thus: Is the chance of ill which may proceed from merely denuding the dura mater, equal to that of its not being so hurt by the blow as to inflame and suppurate? Or is the mischief which may be incurred by mere perforation of the skull, equal to the good which it may produce? These questions, let those who have seen most business of this kind, and who are therefore the best judges, consider and determine.

The third consideration, *viz.* What proportion the number of those who have escaped without the operation bears to that of those who have perished for want of it, is in great measure included in the two preceding; at least the determination of them must also determine this.

"The number of cases of this kind (says Mr Pott) which are necessarily brought into a large hospital so situated as Bartholomew's is, in the middle of a populous city, where all kinds of hazardous labour are carried on, has enabled me to make many observations on them; and although I have now and then seen some few of them do well without the use of the trephine, yet the much greater number whom I have seen perish with collections of matter within the cranium, who have not been perforated, and for whom there is no other relief in art or nature, has, I must acknowledge, rendered me so very cautious and diffident, that although I will not say that I would always and invariably perform the operation in every case of simple fracture, yet the case must be particularly circumstanced, the prospect much fairer than it most frequently is, and my prognostic delivered in the most guarded apprehensive manner, when I omit it. I should be sorry to be so misunderstood as to have it supposed that I mean to say, that I think the denudation of the dura mater a matter of absolute indifference, or that no ill can proceed from it. This I know is a point concerning which the best practitioners have differed, and concerning which we will stand in need of information; but I think I may venture to say, what is fully to my present purpose, *viz.* that enlarging the opening of a fracture by means of a trephine will not produce or occasion much risk or hazard additional to what must be occasioned by the fracture itself: that has already let in the air upon the membrane; and therefore that consideration is, at least in some degree, at an end, and the principal point to be determined still remains the same, *viz.* Whether, upon a supposition that the dura mater may possibly not have been so injured as to inflame and suppurate in future, the operation ought not to be practised as a preventative, but, on the contrary, ought rather to be deferred until worse symptoms indicate the necessity of it? or, Whether it ought in general to be performed early, in order, if possible, to prevent and guard against a very probable as well as very terrible mischief?

"I know that it may be said, that a fracture, if of any considerable size, or whose edges are fairly distant and unconnected, will of itself make some way for discharge from within: and so it certainly may and does, in the case of an effusion of fluid blood; but even in this it very seldom proves sufficient for the purpose. But

does

does not the distant separation of the edges imply greater separation of the attaching vessels of the dura mater? and does not experience too often prove this to be the case? In truth, the great advantage which is sometimes derived from considerable fractures, is most frequent in those cases where portions of bone are so loose as to be removable; which removal of bone stands in place of perforation, and makes much more for the necessity of the operation in other cases than against it, if properly considered.

155
Cases of
contusions
of the head
without any
wound,
mentioned
by Mr Pott.

In confirmation of the above doctrine Mr Pott adduces a great many cases. Of contusions of the head without any wound he mentions five. The first, a man that was knocked down in a mob; he soon recovered his senses, and, after being plentifully bled, was to appearance well in three days. Six days after, he was taken ill with the symptoms of a beginning inflammation of the dura mater; which having continued three days, he was again taken under Mr Pott's care.—It was now twelve days from the accident; and after this the symptoms continually increased until the seventeenth day, when he died. Two days before his death, a tumour, which had arisen on the spot where the injury had been received, was laid open, and a thin brown sanies discharged. The cranium was altered from its healthy appearance, but without fracture or fissure. On opening the head, a considerable quantity of matter was found betwixt the dura mater and the skull under the diseased part, but nowhere else.

The second case was a boy of nine years of age, who had been stunned for a minute or two by a fall from a cart. In two days he seemed to be quite well: but in five days after, that is, in seven from the accident, he complained of the symptoms already mentioned; which having continued for six days longer, Mr Pott was called, and found about a third part of the parietal bone covered with a flatish tumour, containing a fluid. The scalp was now divided, and the cranium found in a diseased state; but a physician who also attended him over-ruled Mr Pott when he intended to perforate it. The child grew worse, and died in three days. On opening the body, a collection of matter was found below the diseased part of the bone; and about the middle of it the dura mater was discoloured and sloughy, containing about a spoonful of matter betwixt it and the pia mater.

In the third case, a labourer fell from a scaffold two stories high, by which he was stunned, but seemed well next day. Five days after, he began to complain of the usual symptoms of an oppressed brain, to which was added a sensation as if a cord was drawn tight round the encephalon; and on the right side of his forehead was a small tumour, which being opened, was found to contain a brown fluid. The bone was diseased, and a circular piece of the scalp cut out. However, as only internal remedies, such as bleeding, neutral salts, &c. were made use of, all the symptoms were aggravated. On the tenth day, the fore was pale, spongy, and glassy, and the scalp separated from the skull to some distance. This day a piece of the bone was removed, and the dura mater under it found smeared with matter. Next day he was worse in every respect; upon which a larger piece of the bone was removed, and a considerable quantity of matter

discharged. The next day, finding his pulse still high and full, ten ounces of blood were drawn off, and a glyster injected. The loss of blood produced a swooning, which lasted some minutes, after which he said he thought his head was easier. As the evening approached, the symptoms returned, and therefore some leeches were applied to his temples. That night, for the first time, he got a little quiet sleep, and in the morning of the 12th day he said that his head was perfectly easy: a very large discharge had been made through the perforation in the cranium, and the wound in the scalp had rather a better aspect. He was kept strictly to a low regimen; took at first the sal absinthii mixture freely: when his pain had left him, his physician ordered him the bark; and in a very few days every bad symptom left him.

The fourth case was a lad of about twelve years of age, who was struck senseless by the blow of a bat on his forehead, as he stood beside a man playing at cricket. A considerable swelling arose on the part: he was treated with bleeding, purging, and the antiphlogistic regimen; and at the end of nine days was discharged as well. In five days after, 14 from the accident, he returned with complaints of an oppressed brain. The symptoms continued to increase, notwithstanding all that could be done, till the 20th, when the forehead which had formerly been swelled and subsided, beginning again to look tumid and puffy, the integuments were divided; the pericranium was found to have quitted its adhesion for more than the breadth of a crown piece, and between it and the bone was a small quantity of thin discoloured fluid. The trephine being applied, a large discharge of matter continued for a week; and the boy again got well.

The sixth case terminated fatally, though the trephine was applied on the tenth day. The patient was a woman, a seller of greens; who, in a quarrel with her husband, had been struck over the head with a moppick. The blow neither fetched blood nor brought her to the ground; and she continued, notwithstanding an irregular life, for a week, without any complaint: she was then taken with the usual symptoms; and, two days after, the operation was performed on one side of the sagittal suture, and close to it. The dura mater was altered from its natural colour, and smeared over with matter. All the symptoms were now aggravated, and a violent erysipelas came on; upon which the trephine was applied on the other side the suture, and the same kind of appearance found as before. The symptoms continued without any abatement; and a third opening being made near to the first, vent was thereby given to so large a quantity of matter, that Mr Pott was convinced the event must be fatal. Accordingly the patient died on the 16th day; and upon opening the head, the dura mater was found covered with matter, under the whole internal surface of both parietal bones; but the firm adhesion of the longitudinal sinus to the sagittal suture had prevented all communication between the two collections of matter.

Of seven cases of contusion with one or more wounds, 156 mentioned by the same author, four died, notwithstanding the operation being performed; the collections of matter being so large, or so situated, that it was impossible to give vent to it by art. One of these

Theory.

cases was remarkable, as it shows the difference between symptoms arising from an injury done to the brain at the time the contusion is received, and that which spontaneously follows the inflammation of the dura mater: we shall therefore give it in Mr Pott's own words.

257
A remarkable one.

"A fireman who was at work on the top of an house, fell in with the roof of it; he was taken out senseless, and brought in that state to the hospital.

"He had on different parts of his body several wounds and bruises, but none of them seemed to be of any great consequence. On his head were four, one of some size, on the upper part of the frontal bone, near to the coronal suture; two on the left parietal; one on the right side of his head, just above his ear; and a small bruise on the upper part of the os occipitis. Of all these wounds, the pericranium was divided in one only, viz. that near the coronal suture.

"His wounds were dressed, he was largely bled, a glyster was thrown up, and a purging mixture was ordered to be used *coelebratim*, until he should have a discharge *per anum*. The next day he was in the same state, perfectly senseless, had the apoplectic stertor, a full labouring interrupted pulse, and some difficulty of respiration. He had four or five large stools; wherefore his mixture was discontinued, but sixteen ounces more of blood were drawn from one of the jugular veins; which evacuation was repeated again in the evening of the same day, to the quantity of eight more. On the third day, being still perfectly stupid, discharging both urine and fæces involuntarily, and having still a full labouring pulse, both the temporal arteries were opened, and fourteen ounces drawn from thence. On the fourth, finding no alteration, and being satisfied that the man's state could hardly be made worse, I determined to perforate the cranium; and accordingly set a large trephine on the upper part of the frontal bone, where the pericranium had been divided. The dura mater was found to be thinly covered with grumous blood, some of which I removed, and thereby made way for the discharge of more. The next day (the fifth), finding that what discharge had been made during the night was bloody, and that the man was in no respect altered for the better, I thought I had sufficient authority for repeating the operation; which I accordingly did, close by and below the former; and as the blow by which the wound had been inflicted seemed to have been almost exactly on the top of his head, I made a third opening in the parietal bone, close to the suture. The appearance under all was the same as under the first, viz. a thin layer of grumous, or rather coagulated, blood.

"Next day (the sixth), toward the evening, the man opened his eyes; and on the seventh, in the morning, he spoke. The discharge of blood continued for several days, and at the end of about a week from this time ceased; the dura mater and the wounded scalp wearing as good an aspect as could be wished, and the patient being easy and rational.

"On the 18th day, he complained of pain all over the head; was sick, reached to vomit, and said that he was faint and chilly. On the 19th, his face was flushed, his skin hot, his pulse quick and hard. He was let blood, and ordered to have a glyster, and

to take some medicines of the febrifuge kind. A day or two more passed in this manner, his fever not violent, but rather increasing than remitting; his pain, though not acute, yet such as to deprive him of his sleep; little rigors occurring irregularly, no perspiration, and an excessive languor. At last, on the 21st day, on the upper part of the os occipitis, on the right side, where there had been a small bruise, a tumour arose, so characterized as to satisfy me that the cause of the late alteration of circumstances lay underneath it: it did not rise to any height, and contained a small quantity of sanies, but covered a portion of bone which the pericranium had quitted. I removed the scalp, and would have felt on a trephine; but the man obstinately refused to submit to it.

"On the 25th day he lost the use of his left leg and arm, and was much convulsed in those of his right side; which paralysis and spasm continued until the 27th, and on the 28th he died.

"Upon examining his head, a collection of matter was found under the bare part of the occipital bone; the dura mater under this matter was sloughy and putrid; and about a desert-spoonful of matter lay between the meninges, just under the altered part of the dura mater. In the part where the bloody extravasation had been, every thing was perfectly fair and free from disease.

"In this case, there seems to have been as clear a distinction between the bloody extravasation, with its effects, and the inflammatory state of the dura mater, with its consequences, as can be desired. All the first symptoms were such as were caused by mere pressure of the extravasated blood; an obliteration of every sensible faculty, attended with the principal symptoms of an interrupted circulation. Perforation of the skull, where this extravasation had been made, did, by giving discharge to the blood, happily remove these; and the man was getting well apace, until the ills arising from another cause, viz. the inflammatory secession of the dura mater in consequence of contusion, and that in another place, began to appear: they indeed made their attack rather late, nor did they rise so high as they most frequently do; but then it must be considered what discipline the poor man had undergone, and what evacuation had been made. Notwithstanding which, they bore their true, genuine, febrile, inflammatory character, and produced their most frequent event. What perforation of the os occipitale might have done, I cannot say; I fear but little, as the matter was not only upon but underneath the dura mater, and that too diseased."

Of the caries of the cranium, mentioned n^o 129. ¹⁵⁸four Cases of a caries of the cranium.

examples are brought; of which only one terminated fatally, at least from the apparent injury done to the brain; although another died of a peripneumony, after every thing seemed to be in a fair way. In this last the trephine was applied upon the carious part of the bone; but in the other three it separated spontaneously.

Twelve cases are related by our author of fissures and fractures of the cranium without any depression, and of these six recovered, and as many died. ¹⁵⁹Of fissures and fractures without depression. The symptoms were generally the same as in contusions without fractures. In one case, indeed, where a girl of 16 had got a violent blow on the head with an iron poker, she had a large wound on the top of her head,

head, with a considerable fracture on the sagittal future. The broken pieces were so large and so loose that they were removed without any perforation, by which the longitudinal sinus was left bare for at least two inches in length; but no hæmorrhage followed from the removal of the fragments.—For three days she was bled twice a-day from one part or other, and stools were procured: but all to no purpose; she still remained quite insensible. On the fifth day an opening was made with a lancet into the longitudinal sinus, and the blood suffered to run off, until her countenance, which had been much flushed, became pale; her pulse, which till then had been full and strong, faltered considerably, and she showed all the marks of a deliquium from inanition. A bit of lint was then put on the orifice, and the nurse was ordered to keep her finger on it, till Mr Pott had visited the other patients in the house. On his return, the part showed no disposition to bleed again, nor did it ever after. That afternoon she opened her eyes, and moved her arms, and the next morning was sensible enough to ask for drink. She retained her senses for some days: but a fever coming on, she became delirious and convulsed; and thus died on the 17th day. On opening the head, a considerable abscess was found on the surface of the brain, on one side of the falciform process of the dura mater.

In another case, though the skull was fractured, none of the bad symptoms appeared till five weeks after the accident. The patient was a lad of about 22, who had fallen from a high scaffold. In his head he had suffered no apparent injury; but the radius of the right arm, the tibia and fibula of the left leg, together with one or two of the ribs, were broken. In five weeks he was permitted to get out of bed; but the first day of his rising he complained of being sick and giddy, which was imputed to weakness and confinement, and therefore disregarded. For three or four days he complained of continual pain in his head, got no sleep, and was constantly feverish. As no injury in the head was suspected, nothing was prescribed but the common antiphlogistic regimen. At the end of the sixth week he complained that his head was painful to the touch; and the day after he made this complaint, had a rigor which lasted half an hour. At last a swelling, which evidently contained a fluid, appeared on the side of the head; and upon opening it, a fracture of the parietal bone, at least three inches long, was found, through which matter issued freely. The trephine was applied, a large quantity of matter discharged, and the dura mater was found sloughy. Under this sloughy part was another collection of matter between the membranes, and below this the brain was considerably discoloured. The patient died on the 50th day after the accident.

In two cases in which the skull was fractured, the patients recovered without the least bad symptom from first to last; and though the operation was performed, Mr Pott is of opinion that they would have recovered without it: however, such cases are but rare; and it is by no means prudent to delay the operation, though no threatening symptoms occur even for a very considerable time.

160
Of fractures with depression. When fractures are attended with a depression of the bone, they are attended with all the danger of the

foregoing classes; with this addition, that the depression is attended with some urgent symptoms, which yet may generally be removed by elevating the depressed parts: yet this ought not to prevent every possible method being used for avoiding the others which appear afterwards, and which are not the less sure on account of the cranium being fractured and depressed. The generality of writers have contented themselves with directing us to raise up the depressed parts, and thereby to endeavour to remove such symptoms as are caused by the mere pressure which the bone makes on the brain: but they have either totally neglected, or very slightly passed over, what is of full as much consequence to the patient; we mean the injury which is most frequently done to the membranes of the brain, and which, if neglected, will certainly produce that fever and those symptoms which so often baffle the whole power of medicine.

The combination of different ill effects, proceeding from the same primary violence, and concurring in the same subject, together with the great difficulty of distinguishing them from each other, is one of the principal causes of that perplexing uncertainty attending wounds of the head. When one cause of bad symptoms has been removed, another, or even several others, may still remain, each of which singly may be sufficient to destroy the patient: and therefore, although the means first made use of may have been such as have been pointed out by the earliest and most alarming symptoms, and extremely proper for the relief of such complaint, had it been the only one the patient laboured under; yet, in the case of a complication, by not being sufficient to answer every requisite intention, they very often answer none, at least not effectually; and, producing only a temporary and partial relief, prove a greater aggravation of our disappointment.

This every practitioner should know, and this the friends of every patient should be made acquainted with; lest the former, being deceived by an appearance of amendment, be induced to promise what it will not be in his power to perform; and the latter, having had their hopes exalted, should be the more severely hurt by their disappointment.

If the fracture be but small, the depression little, and the force with which it was produced not great, the elevator introduced through the perforation may be sufficient to set it to rights; and, if there be no urgent symptoms, nor any mischief done to the internal parts, may be sufficient for all purposes. But if the force was great, if the symptoms are immediate pressed or pressing, if the fracture runs in a form inclined to a circular one, or if the depressed piece be cracked all round, the best and safest way is to remove the whole or greater part of the portion so depressed and ved. circumscribed.

To those who are unused to things of this sort, so large an opening as such method of acting must make will have a very tremendous appearance; and they may be inclined to suspect much hazard and inconvenience from laying bare so large a portion of the dura mater: but let all such remember, that however large the quantity of membrane may be which shall be thus denuded by the operation, yet the same quantity at least, most probably a much larger, would in all like-

likelihood become inflamed, and generate matter on its surface; which matter, for want of a timely, ready, and sufficient outlet, would do considerably more mischief than the mere detection of the said membrane can do.

164
Why the broken pieces of the cranium are to be removed.

In cases where the broken pieces of a depressed fracture are widely separated from each other, and some of them a good deal loosened, the expediency and the propriety of removing such pieces is acknowledged by every body; but few people attend to the reason, or inquire why such practice is just and proper; if they did, they would also see, that the free removal of bone was equally proper in the case of great violence, as in that of loosened or widely separated pieces. In the latter, the broken parts are removed, because their re-union with the rest of the cranium, and the preservation of the attachment of the dura mater to the inner surface of them, is thought impossible, or at least highly improbable; and that therefore they must be in the way, and hinder the free discharge of matter from the suppurating membrane. And is not the same inconvenience full as likely to attend the former? Is it the violence done to the bone, and through it to the membrane, which causes the inflammation and suppuration? or is it the loosened or separated state of the broken part? If it be the former, (as it most undoubtedly must be), the same precautions, the same method of treatment, must be equally necessary in the one as the other; the reasons, the intentions, are the same in each; and if the conduct be not the same, the patient will suffer.

The peculiar circumstances of each individual case must furnish direction to the practitioner for his particular conduct. Rules to be laid down by a writer on such subject can be only general. The parts which are depressed must be elevated; such as are loose and cannot be brought to lie even, such as cannot be prevented from pressing on the membrane, or such as wound or irritate it, must at all events be taken away; the free discharge of blood or lymph in present, and of matter in future, must be provided for; and therefore every symptom and appearance must carefully and early be attended to, lest the most proper opportunity of giving assistance be not embraced.

165
Cases of fractures with depression.

Of four cases related by our author of fractures with depression, two recovered, and two died. The first, who was a girl of about 15, being tossed by an ox, and falling with her head against the bones, got a fracture with considerable depression. It traversed the os parietale from before backward, in its middle part between the sigmoid and temporal sutures, and the depression was on the upper part of the bone. The whole was reduced to a perfect equality, the bone being trephined on the inferior and undepressed part. Her head was dressed lightly, and about 16 ounces of blood taken from her. She passed the following night very unequally, and the next morning was still insensible. She was again freely bled, and a purge was given, which soon operated. On the third day she was bled again, on the fourth she became sensible, and on the fifth was surprisingly well: but on the ninth she began again to complain of headach, sickness, and giddiness; and, notwithstanding all the internal remedies which could be used, growing constantly worse, she died in 20 days from the time of the accident. All the internal surface of the os pa-

rietale above the fracture was detached from the dura mater, and covered with matter, which could not be discharged at the perforation, the membrane being inflamed and thrust tight up against it. On this case Mr Pott remarks, that though he will not pretend to assert that repeated perforations of the upper part of the bone would have preserved her; yet it would have been her best, if not her only chance; and that if he had at that time known as much as afterwards, he should certainly have taken away the greatest part, if not the whole, of what had been depressed.

We have already observed, that the very worst symptoms, nay, even death itself, may frequently proceed from an extravasation of the fluids within the cavity of the cranium, or from a concussion of the brain itself.—Extravasations of any kind, and wherever situated, within the cranium, are very hazardous, and much more frequently end fatally than happily: but, considered as relative to the art of surgery, that which consists of merely fluid blood situated between the cranium and dura mater is certainly the best, as it is the nearest to the surface, and admits the greatest probability of being relieved by perforation of the skull; grumous or coagulated blood, although in the same situation, by being most frequently adherent to the membrane, is not so readily discharged as the preceding, and therefore more likely to prove destructive; and all those which are either under the meninges, or within the cavities or substance of the brain, as they are very seldom within our exact knowledge, so they are also generally beyond the reach of our art.

The method of treating people under these unhappy circumstances is somewhat different, according to the supposed or most probable nature of the complaint, and according to the symptoms and appearances which it produces or which accompany it. When the symptoms which imply a pressure made on the brain or nerves have been occasioned merely by a shake or concussion, and neither blow nor other external violence has been offered to or received by the head, we have no rule whereby to form any other than a general opinion; no mark which can point out to us either the precise nature of the disease, or its particular situation; consequently we have no direction from what part of the head to remove the scalp, or where to apply a perforating instrument, and therefore no authority for perforating at all. In this case, the only chance of relief is from phlebotomy and an open belly; by which we may hope to lessen the quantity of the circulating fluids as to assist nature in the dissipation or absorption of what has been extravasated. This is an effect which, although not highly improbable in itself, yet is not to be expected from a slight or trifling application of the means proposed. The use of them must be proportioned to the hazard of the case. Blood must be drawn off freely and repeatedly, and from different veins; the belly must be kept constantly open, the body quiet, and the strictest regularity of general regimen must be rigidly observed. By these means, very alarming symptoms have now and then been removed, and people in seemingly very hazardous circumstances have been recovered. Instances of these successes are not indeed so frequent as we could wish; but they have been sufficiently so to warrant the attempt, especially in cases where there are no indications to authorise the use of any other. But when

the

Theory.

the symptoms of extravasation are the consequence of such external violence as leaves a mark where it was inflicted, and when the scalp is so bruised or wounded as to show the place where, we then have some degree of assistance, both in forming a judgment of the most probable nature of the complaint, and in using the means most likely to prove successful in its relief. For if the effusion has been the consequence of the stroke which the head has received, and such effusion is made immediately under the part so stricken, the perforation of the cranium in this place may give discharge to the extravasated fluid; and the wound or bruise in the scalp shows us the point from whence we ought to remove a portion of it, in order to perforate the cranium. This is sometimes the case; and the consequence is sometimes so fortunate, that we save a perishing patient. But although it does now and then happen that we are so lucky, yet such success is by no means certain or to be depended upon. Every thing relative to this kind of disorder is fallible and uncertain; and though the extravasation is sometimes found immediately under the external mark, yet it often happens that it is not, and that the effusion is made in a part distant from that mark, and to which we have nothing to lead us. Upon the whole, although a bruise or wound of the scalp does not in these cases necessarily or certainly point out the seat of an extravasation; yet when bad symptoms urge, and evacuation hath been fully and unsuccessfully tried, such mark may be deemed a sufficient, though not unerring, authority for making farther inquiry, by removing the scalp and perforating the cranium: for this is a kind of case in which we are not to expect certainty, and in which we must be content with such information as we can obtain. The opportunities which we have of being serviceable are but few; we should therefore suffer none to escape, but embrace every possibility. The general advice given by Fabricius ab Aquapendente is applicable to no part of surgery more than to this; in which the loss of a very short space of time is often absolutely irretrievable.

If the extravasation be of blood, and that blood be in a fluid state, small in quantity, and lying between the skull and dura mater, immediately under or near to the place perforated, it may happily be all discharged by such perforation, and the patient's life may thereby be saved; of which many instances are producible. But if the event does not prove so fortunate, if the extravasation be so large or so situated that the operation proves insufficient, yet the symptoms having been urgent, general evacuation having been used ineffectually, and a wound or bruise of the scalp having pointed out the part which most probably received the blow; although the removal of that part of the scalp should not detect any injury done to the bone, yet the symptoms still subsiding, we cannot help thinking, that perforation of the cranium is in these circumstances so fully warranted, that the omission of it may truly be called a neglect of having done that which might have proved serviceable, and, *rebus sic stantibus*, can do no harm. It is very true, that no man can beforehand tell whether such operation will prove beneficial or not, because he cannot know the precise nature, degree, or situation of the mischief; but this uncer-

tainty, properly considered, is so far from being a dissuasive from the attempt, that it is generally a strong incitement to make it; it being full as impossible to know that the extravasated fluid does not lie between the skull and dura mater, and that under the part stricken, as that it does; and if the latter should be the case, and the operation be not performed, one, and most probably the only, means of relief, will have been omitted.

Of concussions and extravasations Mr Pott relates ^{Cases of} eight instances; six of whom died, and two recovered. ^{concussion and extra-} The first was a young man who fell from a window-^{vasation.} two stories high, and pitched his head upon a sugar hoghead. He was taken up insensible, and continued so for five days; at the end of which he died, notwithstanding he had been very largely bled. No external mark of violence was observed on the head; the cranium was nowhere injured; the dura mater was every where adherent, and no fluid of any kind betwixt it and the skull. Between the dura and pia mater was a considerable quantity of blood, principally towards the lower part of the brain.

The second case was very similar; the patient expired on the third day, without having shown any signs of sense. All the space between the frontal bone and the dura mater was covered with grumous blood, firmly adherent to the membrane.—In the third, a small tumour appeared on the right side of the head, which thus indicated the seat of the mischief; and, by perforating the skull, a large quantity of blood was discharged between the dura mater and the skull; after which the patient recovered. The fourth was much the same; a tumour appeared on the right side near the sagittal suture; which indicated the application of the trephine. Thus a considerable quantity of blood was discharged, and the patient soon recovered.—The fourth case was remarkable, as showing us how very small contusions of the head will sometimes do irreparable mischief. A boy between three and four years of age, when at play with his brother, fell from a bed on a soft carpet. He pitched on his head, and immediately complained of being sick and giddy; but having vomited, was soon after so well, that no farther notice was taken of his fall. On the fourth day after this, he again became sick and giddy. The physician who prescribed for him gave him an emetic, and some of those medicines called *nervous*; however, his sickness and giddiness now and then returned, with a great aversion at motion of any kind. On the 11th day he lost his sight; on the 13th the use of his right arm; on the 15th he could not stand; and on the 18th he died. A considerable quantity of bloody serum was lodged between the dura and pia mater about the basis of the brain.—In the fifth case, the patient continued 12 days without any general complaint; but on the 13th became giddy and dim-sighted, and soon after died. The ventricles of the brain were full of extravasated serum, and near the origin of the medulla oblongata was a lump of firmly coagulated blood.—The seventh and eighth cases were not materially different; the patients both died comatose; and extravasations of blood, serum, or lymph, were found in both.

When the brain itself is wounded, the treatment ¹⁶⁹ Of wounds can only be to remove all such parts of the broken in the brain. Skull as may continue to injure the brain or its mem-^{branes.} ^{branes.}

Theory.

Theory.

branes; to take away all such extraneous bodies as can easily be got at and extracted without violence; and to make such openings in the cranium as may best serve for the discharge of extravasated fluids, either immediately or at any future period. When fungi of the brain protrude, it is usual to tie a thread round their neck, upon which they drop off spontaneously.

In contusions of the head, whether attended with fractures or not, Mr Bromfield recommends the use of opium; and insinuates, that most of those patients die who are treated only with evacuations and the antiphlogistic regimen. The medicine he recommends is Dovar's powder; and the effect expected from it is a diaphoresis. For this the warm bath is in general a good preparative, as it promotes perspiration: and should the patient be relieved, the diaphoresis is to be kept up by medicines of a similar kind; such as vinum antimoniale with the tinctura thebaica. Thus he tells us, that every symptom of concussion of the brain has in general gone off on a plentiful sweat being produced by the powder. The medicine was generally continued as the symptoms required, till the patient seemed out of danger; and where they returned again, the medicine was repeated, and the patient did well. In support of this practice, he gives the following instances.

271
Examples
in support
of the prac-
tice.

"A gentleman received a violent blow on the top of his head from a large weight falling on it, which fractured his skull and depressed it. I attended at the operation, when every possibility of future pressure on the brain from the fractured bone was entirely prevented by the removal of the depressed pieces. He took Dovar's sweating powder, which, he said, always relieved him when it began to operate. He had stools as often as was thought necessary, and was bled very freely before I saw him. As the wound did not begin to digest kindly at the usual period, in the intermediate time between the sweats, he took the sal abstin- this neutralized with succ. limonium, and a decoction of the bark. About the fifth day he grew comatose; and the gentleman whose patient he was seemed to wish he had been bled again. I desired him to recollect how constantly we consulted the pulse when we met; and that he had always told me, that in my absence he was never induced to bleed him from fulness; and from the quiet state of his pulse whenever we met, we judged it unnecessary. This he allowed; but as the coma was great, I consented to his losing some blood from the jugular vein, which did not make his pulse flag, nor was he relieved by the bleeding. When I saw him the next day, being the sixth from the accident, he was dying. I did not see the patient after he died; but conclude, that the brain had suffered so much from the violence of the blow, that let what method soever have been followed, the event in this case would have been the same.

"John King, aged 35 years, having fallen from a scaffold, was brought to St George's hospital on the 8th of May 1771, quite senseless. He had received by the fall two large wounds; one on the anterior, the other on the posterior part of his head, and his back was violently bruised: he had bled a little at his nose. Immediately after his admission into the hospital he was let blood; and from the administration of a clyster had two stools, and took a scruple of Dovar's sweating powder. On the ninth he was more sensible,

and complained of great giddiness, with pain in his forehead and back. He was then ordered to take 10 drops of the tinctura anodyna antimonialis once in four or six hours, as the effect might indicate; a somentation was applied to his back, a stool procured in the evening by a clyster, and Dovar's powder was repeated at bed-time. On the 10th the giddiness was gone off, the pain was abated, and his head was perfectly easy; the use of the tinctura anodyna was continued, and his body kept open by a laxative mixture. On the 11th he was free from all complaints; granulations began to appear on the wound, which looked well; and the use of the drops was discontinued. He remained well till the 16th; about which time he was seized with giddiness and a sickness at his stomach. Eight ounces of blood were then taken away, and some stools procured by a purging draught. On the 19th the giddiness and sickness entirely left him. On the 21st his sickness returned, with great pain in his head: he was then directed to take a scruple of Dovar's powder at night. On the 26th all his complaints were gone. He was then ordered to take four spoonfuls of the following medicine once in four hours: Sal. abstin. ℥iij. succ. limon. ʒi. decoct. cort. Peruvian. ʒxiv. He remained without any return of his complaints, and was discharged on the 12th of June.

"Patrick Darbun, aged 26 years, was admitted into St George's hospital the 6th of July 1771, having a large wound on the fore-part of his head, and some slight bruises in different parts of his body. He had fallen from a scaffold. It was about an hour after the accident when he was brought to the hospital, where the surgeon was informed that he had continued senseless for half an hour after the fall, and had vomited twice. He had great pain in the parts that were hurt, with stupor and heaviness. Upon a careful examination of the skull, no fracture could be discovered. Some blood had been taken away before he was brought to the hospital, where a purging mixture was given him, and some stools thereby procured. He then took a scruple of Dovar's powder. He complained of great pain in his head and giddiness on the seventh, and had had but little rest. The tinctura anodyna antimonialis was given him, 10 drops of which he took once in four or six hours. He was rather easier in the evening, and the pulv. Dovar's was repeated at bed-time. On the eighth he was much better; the use of the drops was continued. On the ninth the pain in his head and giddiness were quite gone. He continued to take the drops till the 12th; about which time, he being perfectly well, no more were given. Having remained in the hospital till the 31st, without any return of his complaints, and the wound being nearly healed, he was made an out-patient by his own desire, and continued perfectly well.

"John Hyde, a boy about 14 years of age, was, on the 7th of June 1771, admitted into St George's hospital, on account of a hurt he had received on his head by falling backwards. The scalp was much swelled, but without any wound: he complained of giddiness, and vomited frequently. The surgeon made an incision into the tumified part, by which the skull was laid bare, and a fracture, of about an inch in length, discovered upon the superior part of the occipital bone. Some stools were procured as soon as it

Theory.

Theory.

was possible by a purging mixture, and afterwards one scruple of Dover's powder was given. He had a pretty good night; and on the eighth the vomitings ceased, though the pain in his head and giddiness continued. He was that day directed to take 10 drops of the tinctura anodyna antimonialis once in six hours. His giddiness went off entirely in the evening; but he complained of a little pain in the fractured part. A stool was procured by a clyster, and the use of the antimonial anodyne was continued. On the ninth he was free from pain, and took the antimonial anodyne once in six hours till the 11th; during which time he was perfectly well, and afterwards was directed to take the neutral mixture, with a decoction of the Peruvian bark. This course he pursued for about a week, and on the 26th was made an out-patient. In about three weeks after this, the wound was healed, and the boy perfectly recovered."

175
of gunshot
wounds.

We shall now proceed to the treatment of gunshot wounds; in which, as the body is frequently mangled in the most dreadful manner, the surgeon must exert the utmost of his skill both with regard to external and internal remedies. In those made by a musket or pistol ball, the most immediate considerations are, To extract the ball, or any other extraneous body which may have lodged in the wounded part; and to stop the hemorrhage, if there is an effusion of blood from the rupture of some considerable artery.

173
of extract-
ing the
ball.

As to the first, viz. the extraction of the ball, it is frequently necessary to enlarge the wound in order to answer this purpose; and if the ball has gone quite through, both orifices are to be dilated (provided the situation of the part wounded will admit of its being done with safety); and particular care is to be taken to preserve both openings, especially that which is the most depending.

In order to get at the ball, or any other foreign matter, probing is to be used as sparingly as possible; and this must evidently appear to any one who will only consider the nature of the symptoms attendant on penetrating wounds of the breast or belly, either from a bullet or sharp instrument; the thrusting in a probe to parts under such circumstances being unavoidably a fresh stab on every repetition of such practice. In wounds of the joints, likewise, poking into them must be equally condemned, as it can never be used without very mischievous and pernicious consequences. And indeed, where probing is necessary, the finger is to be preferred as the best and truest probe, where it is practicable to do so.

If a ball, or any other foreign body, happens to be lodged near the orifice, or can be perceived by the finger to lie under the skin, though at some distance from the mouth of the wound; in the first case it is requisite immediately to remove such extraneous matter; and, on the other occasion, to cut upon it and take it out: But when it is sunk deep, and lies absolutely beyond the reach of the finger, we ought never to thrust a pair of long forceps into the wounded body, with scarce any probability of success.

To put this matter in as clear a light as possible, we will suppose a ball to be lodged in any part beyond the reach of the finger, entirely out of the way of being marked by the external touch. Now it will ap-

pear evident, upon the least reflection, that thrusting, first along probe in quest of the bullet, and then, as has been practised likewise, a longer pair of forceps, either with or without teeth, into a wound of that kind, though with a sort of certainty to extract it, must either contuse, or irritate and inflame, the parts to a great degree; and consequently do as much, or more mischief, than the ball did at first by forcing its passage such a length of way. And should they at the same time lay hold of any nerve, artery, or even common membrane of a muscle, together with the ball (which can scarce ever fail of being the case), what shocking consequences would attend such a proceeding! Nor would attempts of this sort be less injurious in case a bullet should happen to be lodged in the cavity of the belly or breast: whereas lead, it is well known, will lie a long time in several parts of the body, without any material hurt, or even inconvenience.

A great number of instances have occurred, where balls have been quietly lodged in several parts of the body, till after many years they have worked themselves a passage towards the surface, and were very easily extracted; and many where balls have been entirely left behind.

176
Of dilating
the wound
&c.

In case the wound be occasioned by a musket or pistol shot, and of course but small, it will be necessary to dilate it without delay, provided the nature of the part (as was before observed) will admit of this with safety: for in wounds near a joint, or in very membranous or tendinous parts, the knife, as well as forceps, should be put under some restraint; nor should any more opening be made than what is absolutely requisite for the free discharge of the matter lodged within. Wounds in the joints are always dangerous, from whatever cause they proceed, whether from a bullet or any cutting instrument: and membranous or tendinous parts, whatever sense of feeling they may be allowed, are yet known, past dispute, to suffer much from their being thus exposed to the impressions of the air.

Whenever the wound is attended with a great effu-
sion of blood, from the rupture of some considerable
artery, it will be absolutely necessary, with all ima-
ginable dispatch, to restrain the bleeding with the
needle; and at the same time to be particularly care-
ful that your hold be not clostive. But the bleedings
from the smaller vessels, in all contused wounds, are of
real service, by unloading the clogged parts, cutting
off the main sources of customary inflammations, and
by that means either totally preventing a fever, or at
least rendering it a symptom of no threatening ten-
dency: an event on which, in an especial manner, de-
pends the future laudable digestion. As for styptic
applications, as we have already observed, there is no
trusting to any of them, where the larger arteries are
concerned. Besides, all such rather retard than pro-
mote the cure: for by obstructing the discharge of the
sanies, which in all large wounds precedes digestion,
the digestion is of course suspended, while the pent-up
sanies becomes a constant additional fuel to the fever.

Where the wounded person has not suffered any
great loss of blood, it will be advisable to open a
vein immediately, and take from the arm a good large
quantity; and to repeat bleeding as circumstances
may require, the second, and even the third day. Re-
peated.

176
Bleeding
when nec-
essary.

Theory.

Theo

peated bleedings in the beginning draw after them many advantages. They prevent a good deal of pain and inflammation, lessen any feverish assaults, forward the digestion, and seldom fail to obviate imposthumations, and a long train of complicated symptoms that are wont otherwise to interrupt the cure, miserably harass the poor patient, and too often endanger his life. And even where the feverish symptoms run high, and there is almost a certainty that matter is forming, bleeding, in that state, is very frequently of great advantage; the matter will be made the sooner for it, and the quantity of it will be less. The following instance, says Mr Ranby, in some measure demonstrates the necessity of bleeding freely as soon as possible.

277
A remarkable case.

"A young gentleman, a cornet of dragoons, was wounded by a musket-bullet just below the knee, on the inside. The ball had made a great laceration in the skin, and laid the membranes bare about four inches in length. The surgeon did not see him till two days after the injury. He was then very feverish, quite parched up with thirst, and had a full pulse, with great pain, swelling, and inflammation all round the joint. Immediate bleeding was ordered, a cooling regimen, with proper dressings, an emollient clyster, and an opiate. The next day his pain rather increased; wherefore he was let blood a second, and after that a third time. Six days were now elapsed when a miliary eruption seized him, with frequent bleedings at the nose, and a diarrhoea, which lasted about ten days. Mean while matter was formed in several places about the knee; which, on being let out, flowed in prodigious quantities. The fever declining, the bark was given him; but as that, though joined with an opiate, ran through him, it was judged necessary to lay it aside. Notwithstanding he was now very weak and low, it was thought, in a consultation, that the only chance which remained of his surviving, was the cutting off his leg. The operation was accordingly performed, but without success. Upon examining the knee, there appeared several cells full of matter communicating with the joint; which had in many places eroded the cartilages of both the great bones."

178
Of the regimen of the patient in gunshot wounds.

For the first twelve days it will be proper to observe a cooling regimen, both in respect of the medicines that may be prescribed, and the diet requisite for the support of nature. It is absolutely necessary, likewise, that the body be constantly kept open. Unless, therefore, nature does this office of herself, a stool should be every day procured, either by emollient clysters, or some gentle laxative taken at the mouth; and whenever there is much pain in the wounded parts, immediate recourse must be had to opium.

179
Of external applications

In respect to external applications, whatever is of a hot, spirituous nature, is remarkably injurious on these occasions; and what no wounded part can in any degree bear. Let the first dressing be with digestive, or lint moistened with a little oil; and a very light bandage made, if it can be readily got, with thin flannel: the next with a digestive warmed, and over it the bread-and-milk poultice, mixed with a sufficient quantity of oil to keep it moist; and where there is great tension, and the wound large, a fomentation should be used. This course is to be continued

till the sore is clean.

This method will commonly promote a constant easy perspiration, abate the pain, very much facilitate the digestion, and remove all apprehensions of any approaching inflammation. The advantage of moistening the lint with oil, is the ease that is procured to a contused wound from such an application, in comparison of one of an absorbent drying disposition; which, instead of giving free liberty to the sanious blood to discharge itself, and consequently preventing an inflammation, by unloading the part, would possibly obstruct the mouths of the capillary vessels, and hinder nature from getting rid of that incumbrance which, it is observable, the very much affects to throw off. We must add here, that tents are never to be made use of where they can be possibly avoided.

Should an inflammation seize any part through the lodgment of a bullet, or any other foreign body, that could with safety have been more immediately extracted, all attempts of dislodging such extraneous matter should be postponed till the swelling has in some measure subsided, and the inflammatory disposition of the fibres is nearly vanished; unless the ball, or other extraneous body, lie at no great distance from the orifice; and there be, on that account, a certainty of removing this incumbrance without any material trouble to the patient.

"If a wound (says our author) be of such a desperate nature as to require amputation (which is always the case when it happens in any principal joint), it would certainly be of consequence could the operation be performed on the spot, even in the field of battle; lest, by deferring it, an inflammation, which one may very reasonably expect, should obstruct a work that ought rarely to be entered upon during the continuance of so calamitous a circumstance. The neglecting this critical juncture of taking off a limb, frequently reduces the patient to a low state, and subjects the blood and juices to such an alteration, as must unavoidably render the subsequent operation, if not entirely unsuccessful, at least exceedingly dubious. And in wounds even where no amputation is required, it is equally advisable not to defer the care necessary to be taken of them; lest, by the parts being exposed to the air, there might arise a series of very dangerous symptoms."

"Wounds that border on any considerable artery, are very apt to bleed afresh upon motion, or the return of a free circulation of the blood into the part, which was interrupted at first by the violence of the injury offered it; and this is almost always the case when the slough begins to separate. For which reason, one should never attempt to remove it by force, but wait with patience till there be a perfect separation of this slough; nor be in the least shocked at the accident of arteries thus opening themselves, which a very moderate experience will convince one to be almost inevitable. The patient frequently gives warning of what is coming upon him, by complaining of great weight and fulness in the limb, which are ever accompanied with more or less pulsation in it: an infallible prognostic of the consequences. Let the wound affect whatsoever part, if these complaints attend it, bleeding and the bark are instantly to be enjoined."

"I

Theory.

Theory.

183
Why a person sometimes dies by losing a small quantity of blood after an amputation.

"I have known (says Mr Ranby) several instances of persons losing their lives from the starting of an artery before the surgeon could reach them; particularly where an amputation has preceded. And I dare affirm, the quantity of blood lost, especially in the case last mentioned, has not amounted to 12 ounces. I do not know how to account for this, otherwise than by the drain which had been made from the mass of blood both before and during the operation; whence a sudden gush (though but a moderate one) of blood, after the great quantity already lost, gives a check to the circulation, and causes immediate death. This reflection, I think, ought to be a lesson of instruction to every practitioner to be particularly intent on the faithful discharge of his duty in regard to tying the vessels."

184
The bark extremely useful in gunshot wounds.

In all large wounds, especially those made by a cannon ball, there is constantly a great laceration of the parts endued with an exquisite sensation. These are ever attended with an excruciating pain, and a discharge of a gleetly matter; which, if not restrained, proves often of the worst consequence, by reducing the patient almost to a skeleton; there being no possibility of receiving a supply of nourishment proportioned to the discharge. In this unhappy state, the bark (in doses of a dram each, and repeated every three hours, or oftener if the stomach will bear it) with surprising efficacy repairs the breach made in the constitution by this terrible havoc. In whatever form it be administered, whether in tincture, extract, or resin, we must ever have an eye to the proportion: for the prescribing it in less quantity is one reason why our expectations are often frustrated, and the medicine brought unreasonably into disrepute; the failure, in point of success, being generally owing to some irregularity in the giving of it, either by under-doing it, or not sufficiently persisting in its use. Elixir of vitriol, taken three times a-day in a glass of water, is of singular benefit, and proves a very good assistant to the virtues of the bark: and if the body be coëstive, to each dose of the bark four or five grains of rhubarb must be added, till that inconvenience be remedied. Should the bark run off by more than four or five successive stools, this effect of it will be checked by a few drops of laudanum, or two spoonfuls of the diascordium mixture along with it, every time it is given.

185
And elixir of vitriol.

Where the fore discharges a considerable quantity of gleetly matter, is flabby, looks pale and glossy, (which appearances are often consequent to a loss of substance), the bark continually relieves the pain that is predominant in this case, and quite changes the complexion of the wound. Nor, in administering it, is the least attention necessary to the quickness of the pulse. And in wounds where, upon every dressing, there has been an oozing from the capillary arteries, like water squeezed from a sponge, subjecting, of course, the patient to no little hazard, the bark, by thickening the matter and lessening its quantity, procures the most surprising good effects.

186
Mr O'Halloran's opinion of gunshot wounds.

On the subject of gunshot wounds Mr O'Halloran observes, that of all the symptoms which attend external accidents, none is more dreaded than inflammation and fever; to guard against which, profuse bleedings, antiphlogistics, diluting liquors, and low diet, are strongly recommended. Yet, necessary as

these means are, we may go to too great excess in them. Inflammation is the natural consequence of every wound, and is absolutely necessary for bringing about the process of healing. The more violent the hurt, the greater is its concomitant inflammation. The latter therefore, so far from being an object of terror, is greatly to be wished for: its absence is always a bad sign; and where it is but flow, the act of reunion or healing is very distant. If, then, a slight inflammation is absolutely necessary to bring a trivial hurt to heal, it must of consequence follow, that a more violent one is requisite to promote a reunion of parts after a more desperate accident. Inflammation therefore should not be hastily repressed: it is a true concomitant on all all hurts; and its excess or absence are the only symptoms of this class against which we should guard.

SECT. III. Of Fractures and Dislocations.

This is one of those parts of surgery which is generally thought to be well understood, and the treatment of broken bones to be very easily learned. Hence we find it practised by those who do not attempt the practice of other parts of the science; yet, notwithstanding these pretensions, it is certain that much attention and care is necessary in reducing fractured and luxated bones, in order to prevent a deformity in the limb, or perhaps worse consequences. The general doctrine of fractures is contained under the following heads, as part of the treatment of them. Extension; counter-extension; coaptation or setting; application of medicaments; deligation or bandage; position; prevention or relief of accidents.

This is the general arrangement of the subject by most of the writers on it, and a very just and proper one it is; but, notwithstanding the parade of books under these various heads, much less alteration will be met with, since the times of Hippocrates, Galen and Celsus, than an inquirer might expect, or than the subject is capable of.

The first article in the general arrangement is extension; under which may also be comprehended the second, or counter-extension. In order to accomplish this, we are directed, if the fracture be of the thigh or leg, to place the patient in a supine posture, and the broken limb in a straight one; than having the upper part of it held firm and steady by proper assistants, we are ordered, by means of hands, ligatures, laces, or even in some cases by pieces of machinery, to make such an extension or stretching of the limb lengthwise as shall enable the surgeon to place the ends of the broken bone in as apt, that is, in as even a position, with regard to each other, as the nature of the fracture will admit.—This is a short description of what in the vulgar phrase is called *setting a broken bone*; and is most commonly a painful operation to the patient, a fatiguing one to the operator and his assistants, and, what is worse, is in many instances found to be inefficacious, at least not fully to answer the intention of the one or the expectation of the other.

Writers in general are very precise and formal in the directions which they have given for the due and proper accomplishment of this purpose. They have told us, that the extension should be made slowly and gradually, and should be continued till the ends of the bone

Theory.

Theory.

bone are separated from each other sufficiently, to admit of the fracture being set without risk of breaking off any points or inequalities, and to enable us to place them perfectly smooth and even. All this, like many other of the preceptive parts of physic and surgery, is very pretty on paper, but not often found to be practicable in the chamber. The directions to continue the extension until the ends of the bones are at a certain distance, lengthwise from each other, plainly implies a considerable degree of violence; the limb must by such force be not only made longer than its fellow, or than nature ever intended it should be; but it is ordered to be executed while the limb is in such position as to put all the muscles most on the stretch, and render them least likely to yield to it.

203
When extension is necessary.

In order to understand the dangers of this method rightly, let us for a moment consider what is or ought to be meant by the terms *extension* and *counter-extension*, and why they become necessary: and here it is plain that neither of them can ever be necessary on account of the mere fracture considered abstractedly. The broken ends of the bone or bones are of themselves inactive; and if not acted upon by other parts, they would always remain motionless. When any attempt is made to put them into motion, they of themselves can make no possible resistance, nor can any be made on their part, save an accidental one, arising from the points of the fracture being entangled with each other; and when they have been once, by the hand of the surgeon, placed properly and evenly with regard to each other, they would of themselves for ever remain so. What then is the reason why fractured bones always suffer a greater or a less degree of displacement? why is a broken limb almost always shorter than its fellow? what creates the resistance which we always find in attempting to bring the fractured parts aptly together? whence does it proceed, that when we have done all that is in our power (according to this mode of acting), the ends of the fracture will, in many cases, become again displaced, and lameness and deformity frequently ensue? In short, what are the parts or powers which act on the bones, and which, by so acting on them, produce all these consequences?

204
The action of the muscles the only obstacles to the reduction of a fracture.

These parts are the muscles, the only moving powers in an animal-body. By the action of these on the bones, all locomotion is performed, and cannot be performed without them: and although all bones, when broken, are in some degree displaced and shortened; yet it will always be found, that in proportion as the muscles surrounding or in connection with a bone are strong or numerous, or put into action by inadvertence or spasm, so will the displacement of the ends of such bone, when fractured, be. The even and smooth position of the fractured ends of a tibia, when the fibula of the same leg is entire and unhurt, that is, when the muscles therefore cannot act upon the former; the visible and immediate deformity when both the before-mentioned bones are broken nearly in the same place, that is, when the muscles can act upon and displace such fracture; the great difficulty frequently met with in endeavouring to get a broken os femoris to lie even tolerably smooth, and to prevent such broken limbs from being much shorter than the others; are, among others which might be produced, such strong and irrefragable proofs as need no comment.

From the muscles then, and from them only, proceeds all the difficulty which we meet with in making our extension; and by the resistance of these, and of these only, are we prevented from being always able to put the ends of a fractured bone immediately into the most apt contact.

Let us in the next place consider what it is which gives to a muscle, or to the principal muscles of a limb, the greatest power of resisting any force applied to them *ab externis*, in order to draw them out into greater length; for, whatever that is, the same thing will be found to be the cause of the different degrees of resistance in setting a fracture.

Does not the putting the muscles in a state of tension, or into a state approaching nearly to that of tension, almost necessarily produce this effect? or, in other words, does not that position of a limb which before we put its muscles into, or nearly into, such a state, give such muscles an opportunity of exerting their greatest power either of action or of resistance? This cannot be denied. On the other hand, what is the state or position of a muscle which is most likely to prevent it from acting, and to deprive it most of its power of resistance? or what is that position of a limb, which in the case of a broken bone will most incapacitate the muscles from acting on and displacing it, and in the greatest degree remove that resistance which they have it in their power to make to the attempts for the reduction of such fracture? Is it not obvious, that putting a limb into such position as shall relax the whole set of muscles belonging to or in connection with the broken bone, must best answer such purpose? Nothing surely can be more evident. If this be granted, will it not follow, that such posture of a broken limb must be the best for making the reduction? that is, it must be that in which the muscles will resist the least, and be least likely to be injured; that in which the broken bone will be most easily set, the patient suffer least pain in present; and that from which future lameness and deformity will be least likely to happen. A little attention to what frequently occurs, may perhaps serve to illustrate and confirm this doctrine better than mere assertion.

What is the reason why no man, however superficially acquainted with his art, ever finds much trouble easy to set in setting a fractured os humeri, and that with very a fractured os humeri. little pain, and a very small degree of extension? Is it not because both patient and surgeon concur in putting the arm into a state of flexion, that is, into such a state as relaxes all the muscles surrounding the broken bone? and is it not for the same reason that we so very seldom see (comparatively speaking of this bone with others) a deformity in consequence of a fracture of it? Let the reduction be attempted with the arm extended from the body, and the difficulty of setting will be much increased: let the arm be deposited in an extended straight position, and the fracture will be displaced, and lie uneven.

Apply the same kind of reasoning to the os femoris; and that bone whose fracture so often lames the patient, and disfigures the surgeon. Will it not be more cogent, and more conclusive, in proportion as the muscles in connection with this bone are more numerous and stronger? Let any man, who has been much conversant with accidents of this kind, be asked, what is the posture

205
Hence the muscles ought to be relaxed attempt the reduction.

206
Why it is that with very a fractured os humeri.

207
And difficult to set the os femoris.

Theory.

Theory.

posture which almost every person whose os femoris has been newly broken puts himself into, in order to obtain ease, until he gets proper assistance? Such people almost always bend their knee, and lay the broken thigh on its outside, because this is the most easy posture, for obvious reasons.

206
When the reduction of a fracture ought not to be attempted.

It is a maxim universally taught and received, that a fractured limb may be in such state as not to admit of the extension necessary for its being set: that is, if assistance be not at hand when the accident happens; if they who bring the patient home do it so awkwardly or rudely as to bruise and hurt the part; if from drunkenness, folly, or obstinacy in the patient, it happens that the limb is so disordered that it is found to be much swollen, inflamed, and painful; it is allowed not to be in a state to admit extension.

207
Erroneous doctrine concerning fractures.

This maxim is indeed founded upon very just principles; but what is the general practice in consequence of it? It is, to place the limb in an extended straight position; to secure it in that; and then by proper means, such as fomentation, poultice, &c. to endeavour to remove the tension and tumor. Now if it be considered that the swollen, indurated, and inflamed state of the muscles is the circumstance which renders extension improper, surely it must be obvious, that such position of the limb as necessarily puts these very muscles in some degree on the stretch, must be a very improper one for the accomplishment of what ought to be aimed at. Under this method of treatment, the space of time which passes in the removal of the tension is sometimes so considerable, that a happy and even coaptation becomes afterwards impracticable; and then this accident, which nine times in ten is capable of immediate relief, is urged as an excuse for unnecessary lameness and deformity.

208
Of the posture of the limb during extension.

Here the nature of the complaint points out the relief. Extension is wrong; a straight position of the thigh or leg is a degree of extension, and a still greater degree of it in proportion as the muscles are in such circumstances as to be less capable of bearing it. Change of posture, then, must be the remedy; or rather the placing the limb in such a manner as to relax all its muscles, must be the most obvious and certain method of relieving all the ills arising from a tense state of them: which change of posture will be attended with another circumstance of very great consequence; which is, that the bones may in such posture be immediately set, and not one moment's time be thereby lost: a circumstance of great advantage, indeed; for, whatever may be the popular or prevailing opinion, it is demonstrably true, that a broken bone cannot be too soon put to rights; as must appear to every one who will for a moment consider the necessary state of the muscles, tendons, and membranes surrounding, and the medullary organs contained within a large bone broken and unset; that is, lying in an uneven irregular manner. In short, if the experiment of change of posture be fairly and properly made, the objections to immediate reduction, from tension, tumour, &c. will most frequently be found to be groundless, and the fracture will be capable of being put to rights, as well at first as at any distance of time afterwards.

209
Reduction ought to be performed as soon as possible.

Extension having been made, and the broken ends of the bone having been placed as smooth and as even

as the nature of the case will admit, the next circumstance to be attended to is the application of some medicament to the limb; particularly to the fractured part of it. In this, different people act differently. Some make use of an adhesive, or what they choose to call a *robortant, plaster*; some, of what is commonly called a *cerecloth*; others apply spirit of wine, with oil, vinegar, and white of egg; and others the *spiritus Mindereri*, the solution of crude sal ammoniac in vinegar and water, or some such kind of medicine. But let the form and composition of the application made to the limb be what it may, one thing is clear, viz. that it should be put on in such manner as that it may be renewed and shifted as often as may be necessary, without moving the limb in any manner; it being certain, that when once a broken thigh or leg has been properly put to rights, and has been deposited properly on the pillow, it ought not never to be lifted up nor moved from it again without necessity, until the fracture is perfectly united; and it is as true, that such necessity will not very often occur. This may perhaps seem strange to those who are accustomed to roll simple fractures, and consequently to lift them up every three or four days in order to renew such kind of bandage; but the necessity of this motion arises merely from the kind of bandage made use of, and not from any circumstance of the fracture itself. That the frequent motion of a fractured limb cannot possibly contribute to the ease of the patient, will be readily admitted; as also it will, that when a broken limb has been once deposited in the best position possible, it is impossible to mend that position merely by taking such limb up and laying it down again: from whence it must follow, that such kind of apparatus as necessitates the surgeon frequently to disturb the limb, cannot be so good as one that does not; provided the latter will accomplish the same kind of cure as the former.

The prevention of a flux of humours to a broken limb by bandage, is a common phrase; but if by the tight bands and edges of the broken bone the muscles and membranes be unavoidably wounded and torn, or if the same kind of mischief be incurred by the inadvertence or indiscretion of the patient, or of those who assisted in getting him home, or from the violence used in extending the limb and setting the fracture, inflammation must be excited, and pain and tumefaction will be the consequence: and these will continue for some time in every fracture; but that space will be longer or shorter in different cases and under different circumstances. Evacuation, rest, and a favourable position of the limb, will, and do in general, remove all these complaints; but bandage can contribute nothing more than by keeping the applications in their proper place; so far from it, that if the bandage be a roller, it must, by the frequent necessity of its being adjusted, and the frequent motion of the limb, in some degree counteract the proper intention of cure.

The old writers are in general very precise as to the number of days during which the roller should be exactness suffered to remain without being shifted, and the number of times which such shiftings should be repeated within the first fortnight. This exactitude is by no means necessary; but if the bandage be supposed to be of any use at all, it is obvious, that it ought to be

210
Proper applications to the fractured limb.

211
Motion to be avoided as much as possible.

212
And too tight bandages.

213
No great necessity in shifting the bandages.

renewed or adjusted as often as it may cease to perform the office for which it is designed, or whenever it shall be found to counteract such office, that is, as often as it shall become so slack as not to contain the fracture at all, or whenever the limb shall be so swollen that the roller makes an improper degree of stricture; the former generally occurs every four or five days, the latter is most frequent within the first week.

214
Superfluous
directions
concerning
them given
by many
writers.

In most of the writers on the subject of fractures, we also find marks or signs laid down for our information concerning the due or undue effect of the bandage on the limb. They tell us, that when that part of it which is below the termination of the roller does not swell at all, the bandage is not sufficiently strict, and will not retain the fracture; that when the same part is considerably swollen, or tense, or inflamed, it implies that the binding is too strait; and that a moderate degree of tumefaction is a sign that the deligation is properly executed.

In consequence of these precepts, many practitioners look more anxiously after this degree of tumefaction, than after the true and exact position of the limb, and cannot be induced to believe that any thing can be wrong under this appearance: although it is plain, that even this degree of swelling is wrong; that it implies some kind of obstruction to the circulation, and cannot serve any good purpose; and consequently, that as far as it may be supposed to be the effect of bandage, so far that bandage must be faulty.

215
Bandages
cannot re-
gulate or
restrain the
callus.

The third purpose for which the roller is said to be used, is the regulation and restraint of the callus.—If we were to form our notion of callus by what the generality of writers have said on this subject, we should suppose, that it was not only a particular juice always ready for the purpose; but that, if not restrained and regulated by art, it would always flow in such quantity, as to create trouble and deformity; that there were specific remedies for increasing or decreasing it, and that it always required the hand and art of surgery to manage it. That the callus is so far a particular juice, as that it consists of whatever is destined to circulate through the bones for their particular nourishment, is beyond all doubt; and that this gelatinous kind of fluid is the medium by which fractures are united, is as true; but that it requires art to manage it, or that art is in general capable of managing and directing it, is by no means true. That this callus or united medium does oftentimes create tumefaction and deformity, or even lameness, is true also; but the fault in these cases does not lie in the mere redundancy of such juice; it is derived from the nature of the fracture, from the inequality of it when set, and from the inapt position of the broken ends with regard to each other; nor is surgery or the surgeon any otherwise blameable in this case, than as it was or was not originally in their power to have

216
Why the
callus some-
times pro-
duces de-
formity and
lame-
ness.

placed them better. It is the inequality of the fracture which makes both the real and apparent redundancy of callus, and the tumefaction in the place of union. When a bone has been broken transversely, or nearly so, and its inequalities are therefore neither many nor great; when such broken parts have been happily and properly coaptated, and proper methods have been used to keep them constantly and steadily in such state of coaptation, the divided parts unite by the intervention of the circulating juice, just as the softer parts do, allowing a different space of time for different texture and consistence. When the union of a broken bone under such circumstances has been procured, the place where such union has been made will be very little perceptible; it will be no deformity, nor will it occasion any inconvenience. It will indeed be discoverable, like a cicatrix of a wound in a softer part: but there will be no redundancy of callus, because none will be wanted; neither will there be a necessity for any particular management on the part of the surgeon, to repress or keep it in order. But when a bone has been broken very obliquely or very unequally; when the parts of a fracture are so circumstanced as not to admit of exact coaptation; when such exact coaptation as the fracture perhaps would have admitted, has not been judiciously made; when, from unmanageableness, inadvertence, or spasm, the proper position of the limb has not been attended to or preserved; in all such cases there must be considerable inequality of surface; there must be risings on one side, and depressions on another; and in such cases the juice circulating through the bone cannot accomplish the union in the same quantity, the same time, or in the same manner. The broken parts not being applied exactly to each other, there cannot be the same aptitude to unite; and according to the greater or lesser degree of exactitude in the coaptation, that is, according as the ends of the bones are or have been placed more or less even with regard to each other, will the inconvenience and the deformity be, and still must, when the fracture is not set at all; but the broken ends of the bone unite laterally, or by touching each other's sides. The periosteum covering every fracture will remain thickened for some time, and a degree of fullness or rising will be thereby caused about the place where such fracture has been united; but time, and the use of the muscles, soon in general remove this.

Two kinds of fracture there are which do not admit of the bent position of the joints, viz. that of the process olecranon at the elbow, and that of the patella: in these a straight position of the arm and leg is necessary; in the former, to keep the fractured parts in contact till they are united; in the latter, to bring them as near to each other as may best serve the purpose of walking afterward (A).

With regard to the fracture of the patella, an opinion

(A) Although a straight position of the limb is necessary for the broken patella, yet this very position becomes so, upon the same principle, as renders the bent posture most advantageous in the broken tibia and femur, viz. the relaxation of the muscles and tendons attached to the fractured bone.

Whoever for a moment attend to the disposition of the pieces in a patella which has been broken transversely, will see how little necessary or useful the many contrivances of bandages, straps, compresses, buckles, buttons, &c. to be found in writers are, especially all that part of them which are applied to the inferior fragment.

By the action of the united tendons of the extensors muscles of the leg, the superior fragment is pulled upward and

218
Why a
fracture of
the patella
frequently
produces a
stiffness of
the joint.

nion has long and generally prevailed, which seems to have no foundation in truth, or even in probability: it is, that the great degree of stiffness in the joint of the knee, which is sometimes found to be the consequence of this kind of fracture, is owing to or produced by a quantity of callus falling into it from the edges of the broken bone; and that the nearer the broken pieces are brought to each other, the more likely such consequence is. But, in the first place, the fractured bone is by no means capable of supplying such a quantity of callus as to produce this effect; in the second place, if this was the case, the most likely, and indeed the only probable way of preventing the deposition of such juice, must be by bringing the broken pieces into close contact; and, in the third place, there is no authority from the appearance of such joints after death, to suppose this to be the case, or to countenance such opinion. The cause, therefore, of this rigidity, which is now and then found to attend the broken patella, must be sought for elsewhere, viz. in the long rest and confinement of the joint, as a means used by many to procure exact union; in mischief done to the ligament, which is formed by the united tendons of the four extensor muscles of the leg, at the time of and by the fracture; and in the nature of the fracture itself, that is, the manner in which the bone shall happen to be broken.

219
What cases
of this
fracture are
most fa-
vourable.

But, be all this as it may, the fact undoubtedly is, that they walk best after such accident whose patella has been broken transversely, and that into two nearly equal fragments; whose confinement to the bed has been short, that is, no longer than while the inflammation lasted; whose knee, after such period, has been daily and moderately moved; and in whom the broken pieces are not brought into exact contact, but lie at some small distance from each other.

220
Of the ri-
sing end of
the broken
bone.

We cannot take leave of this subject of simple fractures without mentioning a circumstance relative to them, which, although, when rightly understood, is of little or no importance, yet, by being misunderstood, becomes frequently of considerable consequence, viz. the use of the term *rising end of a broken bone*.

221
The term
improper.

By the expression, any one unacquainted with these things would be inclined to think, that the prominent part of a broken bone rose or was elevated from its natural place, and became by such rising superior to the other part or extremity of the fracture. This would certainly be the idea of an ignorant person, and as such would be of little consequence: but by the practice of many surgeons, it is as certainly their idea also; and this renders it a matter of great consequence. The truth is, that there is really no rising end to a broken bone, when applied, as the term usually is, to the leg, thigh, and clavicle. There is indeed a superior or prominent end or part, and an inferior or depressed one: but the former of these is in its proper place, from which it cannot by art be moved; and the latter, which is not in its proper place, is very capable by art of being put into it.

When a collar-bone, os femoris, or tibia and fibula, are

are broken by the action of the muscles, by the motions of the patient, and by the mere weight of the inferior part of the arm, thigh, or leg, the fractured ends of such bones are displaced, and always displaced in such manner, that the inequality occasioned necessarily by such displacement, proceeds from the inferior end of the fractured bone being retracted or drawn under the superior. This produces a tumefaction or unequal rising; and the upper extremity of the fracture is therefore called the *rising end of it*. Now the man who regards this rising end as that part of the fracture which has by such rising got out of its place, and not as having accidentally become the prominent part merely by the inflexion or retraction of the other part underneath it, will go to work with bolster, compress, and bandage, in order to bring and keep such end down: by which means he will give his patient considerable pain; and, while he depends on such means alone, will most certainly be frustrated in his intention and expectation, the means not being adequate to the proposed end. But the man who looks on this in the true light, that is, who looks on the superior part as being in its proper place, and the inferior as being displaced by the weight of the limb and the action of the muscles, will know, that by the mere position of such limb, he shall be able to remedy all the inconvenience and deformity, as far as they are by art capable of remedy, without the parade or the fatigue of useless apparatus.

222
We must
not attempt
to depress
the promi-
nent part.

He will, for example, know, that the prominent part of a broken clavicle, that part of it which is next to the sternum, is just where it should be; and that the inferior part, that which is connected with the scapula, is out of its place, by being drawn down by the weight of the arm; and therefore, instead of loading, as is usual, the prominent part with quantities of compress, which never can do any service, he, by a proper elevation of the arm, will bring the lower end upward into contact with the other, and thereby with very little trouble easily accomplish what he never can do in any other manner, however operose.

The same thing will happen, from the same principles, in the leg and thigh. A prominence, or a rising end, there always will be; but that rising end is never to be brought down by any pressure from compress or bandage; the fallen or inferior one must always be brought up to it by the proper position of the rest of the limb: this will always remove the inequality as far as it is removable; and nothing else can.

We come now to speak of *compound fractures*, or those in which the breaking of a bone is complicated with a wound. In this case, the first object is whether the limb can be preserved or not. Many circumstances concur to make this doubtful. For instance,

223
Of com-
pound
fractures.

the bone or bones being broken into many different pieces for a considerable extent, as when a person's limbs are crushed by the wheels of heavy carriages passing over them; the skin, muscles, tendons, &c. the limbs being so much lacerated and destroyed, as to render can- gangrene and mortification the most probable conse-

whether
the limbs
can be pre-
served.

quency; and separated from the inferior; but the latter remains nearly, if not absolutely, where it was before the accident: there is nothing to act upon it; and therefore it cannot, nor does it move.

The extension of the leg puts the muscles attached to the upper part of the broken bone into a state of relaxation, and prevents their acting; and though a small compress just above this piece, with a moderate bandage, may be useful toward retaining it, yet it is the position of the leg which must keep the broken piece down, and effect the cure.

Theory.

Theory.

quency; the extremities forming a joint being crushed, or, as it were, comminuted, and the ligaments connecting such bonds being torn and spoiled, with other circumstances of the same kind, are, by very eminent practitioners, reckoned sufficient reasons for performing immediate amputation. On the other hand, there are not wanting men, whose knowledge in their profession can by no means be doubted, that absolutely deny the usefulness of immediate amputation almost in any case, unless the limb is already torn off and hanging almost by the skin. Mr Boucher, of the Royal Academy of Surgery, gives twelve remarkable instances of desperate fractures in which the limbs were preserved. The first was a shot through the thigh, with a considerable fracture of the os femoris near the condyles. The patient refused to submit to the operation, and was completely cured, but with one thigh shorter than the other, in ten months, notwithstanding the frequent incisions, fever, and large splinters of bone that came away from time to time. The second had a fracture of the lower extremity of the arm, and was also cured without amputation. The third was shot in the fore-arm by a pistol ball, which wounded the internal condyle of the humerus and olecranon; yet the patient not only was cured of the wound in the space of 12 months, but recovered of the ankylosis also. The fourth and fifth were similar. In the sixth, the shot penetrated the lower part of the femur, in which the inner condyle was engaged; yet, notwithstanding a variety of bad symptoms, he obtained a cure in the space of 11 months. In the seventh case, the inferior part of the radius was fractured, with considerable laceration of the tendons; nevertheless this patient also was cured, but with a stiffness in the joint. In the eighth, the ball passed from the malleolus internus through the malleolus externus; yet the patient was completely cured in nine weeks. The ninth patient had received a ball which tore through the deltoid muscle, fractured the head of the humerus, and part of the clavicle. The extirpation of the humerus was judged absolutely necessary, which yet the patient resolutely opposed; and by that means saved his arm, being discharged only with a small fistula, which the warm bath soon cured. The tenth was a soldier, wounded by a musket-ball in the upper part of the humerus, with a fracture of this bone; yet he also got a cure without amputation. In the eleventh, a musket-ball fractured the head of the bone at the elbow. In the twelfth, a ball was lodged in the calcaneum; yet, after extraction, the wound was cured without any bad accident.

Notwithstanding this great success, however, M. Boucher is of opinion, that there are certain accidents which nothing but amputation can remove. Such, for instance, are fractures of the larger extremities, where numbers of splinters stick out, and cannot be removed; when the same bone is fractured in several different places; when the extremity of one of these bones is separated from its body, and shattered in many places; when the wounded parts are seized with violent convulsions which cannot be cured; where the bone is surrounded with loose flabby flesh, and a sanious discharge with acute pain, which indicate the bone to be disordered; and where a sphacelus is formed. Where these symptoms indicate amputation, he thinks that

the sooner it is performed the better; for when it is deferred, he says, the violent irritation of the nervous and vascular systems, which in a short time succeeds the accident, puts the whole animal economy and mass of fluids into such disorder, that the pus requisite for the cure is defective, and the recovery becomes doubtful. And he attributes this want of success where the operation is delayed, not to the first cause, but to the alteration caused by the delay.

On the other hand, M. Faure, in a paper presented to the Academy, attempts to prove, that where amputation is necessary, it ought always to be deferred till the bad symptoms occasioned by the wound have abated. The reason he gives for this practice is, that nature having already sustained a violent shock, is unable to bear the succeeding one arising from amputation: and for the truth of this he appeals to the cases of about 300 persons, who underwent the operation after the battle of Fontenoy, of whom scarce one in ten escaped. Convinced, by this sad example, that amputation had been too hastily performed, he selected ten patients on whom the operation was judged unavoidable, and directed them to be let alone for a month; after which he performed the operation with success on them all. The cases were the worst that can almost be imagined. The first had the head of the os humeri fractured by a cannon-ball, while a complicated fracture of the leg was made by a musket-ball. The others were a complicated fracture of the thigh; a fracture in the articulation of the knee, thro' which the ball passed; a complete fracture of the forearm, which extended to the os humeri; a wound of the inferior part of the forearm, with shivering of the bones of the carpus; a wound at the upper part of the humerus, with a fracture above an inch broad; a fracture of the bones of the carpus; the os calcis shivered, and the tendo Achillis torn; a complicated fracture of the tibia; a fracture of the tibia in which the tarsus was engaged.—From all these cases, M. Faure strongly contends, that where amputation is unavoidable, it should always be delayed till the fever and other bad symptoms cease; and he exclaims against the contrary method; adding, that “we might even say, the sooner the limbs were amputated, the sooner were the patients condemned to death.”

M. Boucher presented a second paper to the Academy, in which he adhered to his former opinion, and gave his reasons for immediate amputation. These were, that at the time of the hurt, or soon after it, the body must be in the best state for enduring the operation; and by neglecting this time, the efforts of nature are useless, and she becomes weaker; the melancholy effects of which, he says, he has been witness of. “For how can we expect (says he) that a body exhausted with pain and misery for five or six weeks, should then be in a better condition to support a terrible operation, than when in full vigour, as must be the case at the time of the accident?” Several instances are adduced in favour of his doctrine; but Mr O'Halloran, from whom we have taken this account, is of opinion, that his reasoning is quite unsatisfactory. “The great point,” says he, “for which M. Boucher contends, is the advantage arising to the patient by having his limb taken off in the first period, or before the fever, inflammation, &c. come on, which

Theory. in themselves endanger the life of the party. But it is highly probable this gentleman never once recollected, that this fever, and all other alarming symptoms, tho' they do not immediately appear, are nevertheless the effect of the derangement in the constitution on receiving the accident: that on this account it is certainly very bad practice to amputate till at least part of these symptoms are abated, for three excessive strong and clear reasons. First, so much depends upon the habit of body, that we cannot be too cautious in our prognostics: for if the slightest hurts, happening in constitutions seemingly sound, are often attended with the most fatal symptoms, in spite of the earliest and best resources of art; how then can we, with any degree of certainty, immediately promise ourselves success, by performing a terrible operation, till we first know if the very juices themselves will not be the greatest obstacle to a re-union? Secondly, how often does it happen, in the best constitutions, that the terrible shock which the whole frame sustains on a violent gunshot wound, nay, even in a fall, without any fracture or visible hurt, that the parts can never recover their tone, and the patient in some days expires? What else are concussions of the brain, violent leaps, where, though the party comes down on his legs, and has no visible hurt, yet dies with all the appearance of a concussion of the brain? What else but the velocity of the circumambient air of a discharged cannon-ball, which, by deranging the whole animal-system, kills the party without sign of hurt? If these account for the death of the patient, will not this be a strong reason for delaying amputation, till we know whether nature is strong enough to recover from this shock, without adding to his misery that of a cruel and terrible operation? Thirdly, let us suppose, to give this gentleman and his partisans argument their utmost force, that happily for the patient, though unknown, or never reflected on by the surgeon, first, that the juices are balsamic and kind; and, secondly, that nature is strong enough to recover from the shock which every accident, more or less, subjects the constitution to: how can we possibly foresee, or at least is not the presumption very strong, that by an immediate amputation, after such a terrible violence as absolutely indicates it, we expose the constitution to the severest trials and the greatest danger possible? If in anchylosis of the tarsus, with great pain, which has reduced the patient very low, we find a severe fever and inflammation ensue, the consequence of the pain and the shock the human frame has sustained by an amputation, how much more is it to be dreaded after a terrible gunshot wound or complicated fracture; which accidents alone bring on all these symptoms in an higher degree? Justly then does M. Faure exclaim, "That the sooner their limbs were taken off, the sooner were they condemned to death!"

"The few instances advanced by M. Boucher, of the success of immediate amputation, for the reasons I have above assigned, can prove nothing for him. If any thing can be granted, it is, that, happily for the patients, their constitutions surmounted the rashness of their surgeons, as well as the severe trials of nature. Amputation, then, should never be practised after sudden accidents, till at least the violence of the symp-

toms proceeding from it are abated, for the reasons assigned, and which I again inculcate; namely, first, till by laudable suppuration we are assured that the juices are balsamic, and which becomes manifest in eight or ten days. Secondly, till we are certain that nature recovers from the shock; which we will also be certain of, by reason's becoming restored if lost, or by the state of the pulses and nervous system: this also becomes apparent about the eighth or ninth day. And, thirdly, till it becomes manifest, that the pain, fever, and inflammation, will not terminate in gangrene, sphacelus, or death. This the state of the pulse and spirits, and the nature of the suppuration, will determine.

"But besides these advantages, at least these points of knowledge gained by the delay, another and a greater also follows; namely, that the abatement of the fever, and the laudableness of the suppuration, are the highest preparations, and the most useful, the patient can possibly have previous to the operation: he is, at the time of amputation, in the same state that we could wish a patient to be in who is to suffer inoculation; and a great degree of certainty attends the recovery of the patient, especially in our method. I shall just single out one observation, which first threw me into this chain of thinking.

"A girl about 16, of a good constitution, some few years past, on Pennywell road, adjoining this city, was accidentally shot in the thigh. The swan-shot fractured the femur at the lower condyles, and the rotula anteriorly, and passed through the parts with a very large wound. In this situation she lay extended on a table for about two hours, when assistance came. Her pulse was regular, she spoke sensibly, and seemed more alarmed than pained. We judged amputation absolutely unavoidable; and her thigh was taken off directly, but she died in about four hours after. Here the death of this girl was visibly hastened, by adding amputation before nature had time to recover from the first accident.

"The truth of this reasoning will appear still stronger by the following observations:

"John Quinlon, a sedan-chairman of this city, in a dispute with another chairman, received a fall by a trip, so that the tibia tore through the flesh at its articulation with the astragal, and reached down a little below the os calcis, and the fibula was consequently terribly fractured. This accident happened the latter end of August 1760. To reduce these parts was absolutely impossible; because a less force than was necessary for this must separate the foot from the leg. Amputation was the only resource left. The man was strong, and about 35 years of age; so that every thing might be expected from the constitution. However, on mature deliberation, though amputation was absolutely unavoidable, I was determined to defer it for some days. Accordingly I laid open the flesh below the protruded bone, and formed an eighteen-tailed bandage, in which, after a gentle extension, I laid the leg, bled the man, and had the parts often wet in brandy. In a few days the inflammation became violent; which was somewhat allayed by bleeding, fomentations, and poultices. In 12 days from the accident, finding the foot gangrened, I determined to amputate. The next morning I performed the operation;

tion; and though, after taking off the limb, some real pus (the remains of the inflammation) flowed from the stump spontaneously, yet did the cure go on as happily as could be wished; and in about ten weeks he was completely cured.

"Alice Blachall, about 15 years old, subject to epileptic fits, and paralytic in the right side, leg, and arm, in one of these fell into the fire, and had the diseased leg so miserably burnt, that the bones of the toes and metatarsus spontaneously dropped off, and those of the tarsus were uncovered and ready to separate. In this condition she was left at our hospital-door July 17th 1762; but with an hectic, lax, and a large discharge from the leg, which was also burnt. This accident happened about 10 days before. The sores, which were filthy, I had carefully stuped, and washed with a decoction of wormwood; and finding amputation absolutely unavoidable, I performed it; and she was discharged, completely cured, in the latter end of the following month, with a firm coat of flesh to cover the extremity of the stump, notwithstanding that this whole side was completely paralytic, and of course the balsamic juices were greatly deficient.

"John Deelan, a poor man, received the fire from a mulket, charged with small shot, in his right hand, and so near, that the wadding rested in the fore. Being recommended to our hospital by the reverend dean Maffy the day after the accident, he was immediately admitted. The little and ring fingers were quite tore off, and hanging by a little flesh; the two metacarpal bones that supported them were also fractured and terribly tore; and the shot was promiscuously thrown into every part of the hand. It was judged impossible to preserve the hand; but, for the reasons already specified, I was determined to defer amputation till the inflammatory state was over. However, I separated the two fingers from the hand; dilated the sores; and extracted a great deal of shot, tow, broken bones, &c. The inflammation which followed was very violent, and extended very high up the arm; but was relieved by profuse bleedings, emollient embrocations, poultices of flummary half-boiled, nitrous medicines, &c. In about 12 days this orgasm was greatly abated; and willing to preserve part of his hand if possible, I extracted the entire remains of the two metatarsal bones, and by this means a great deal more shot, splints, &c.; and, contrary to expectation, this man was discharged with two fingers and part of his hand, with which he has been able to support his poor family since by day-labour.

"One O'Neal, returning from town much in liquor, fell into a sand-pit on the high road near this city, and a very large stone fell on his right leg with such a force, as to fracture the tibia for above three inches in a most dreadful manner, with a wound of a larger surface. Indeed the bone was broke into numberless bits; inasmuch that, considering the length of the fracture, it may be safely affirmed, that a quarter of an inch of it was not entire. He was carried to the turnpike-house, and I was sent for. On the spot I prepared an eighteen-tailed bandage, dilated the wound, extracted a great many loose bits of bone, dressed with soft lint, and bled him. Next morning he was brought to town on a door, and dressed lightly

for some days, till the state of inflammation was somewhat abated; when I determined to take off his leg, which was judged impossible to be saved: and I dare say, from this slight description of the case, every surgeon would conclude the same. Nevertheless, so bountiful was nature in this case, and so strong in her resources, that in four months from the accident, this man could use this leg, and is now a living witness of this truth. So that, besides the reasons already advanced, we have a chance for one more, and that the greatest, advantage to the patient, namely, the chance of saving the entire limb by delaying the operation.

"But as M. Faure does not absolutely determine the precise time of performing the operation after the accident, and that by the delay of six weeks, or till the symptoms cease, numbers of lives must be lost, I observe, that this is very vague and uncertain; because, by the nature of the accident, many symptoms must subsist, even after the general inflammation is passed. Such are extraneous bodies constantly irritating, splints of bones, too abundant suppuration, &c. In such cases, it will be in vain to expect an abatement of symptoms till the cause of them is removed, namely, the limb taken off. Upon maturely, then, considering the whole affair, I boldly affirm, that the shock from the general inflammation, the patient's state of blood and habit of body, &c. will be thoroughly known in about 20 days from the accident; and every symptom that continues subsequent to this must take its rise from the sore itself, and that where amputation is absolutely unavoidable. Supposing the patient to be treated all the time preceding this according to the rules of art, it should not be deferred longer, lest the patient sink under it. By this means, instead of about one in three amputated patients recovering, we should scarce lose, almost to a certainty, one in twenty."

Mr Pott seems to be an advocate for immediate amputation, or at least to dread none of those fatal consequences from amputation which we have just now mentioned. His words are, "When a surgeon says that a limb, which has just suffered a particular kind of compound fracture, ought rather to be immediately cut off, than that any attempt should be made for its preservation, he does not mean by so saying, that it is absolutely impossible for such limb to be preserved at all events; he is not to be supposed to mean so much in general, though sometimes even that will be obvious: all that he can truly and justly mean is, that from the experience of all time it has been found, that the attempts to preserve limbs so circumstanced, have most frequently been frustrated by the death of the patients in consequence of such injury; and that from the same experience it has been found, that the chance of death from amputation is by no means equal to that arising from such kind of fracture."

"Every man knows, that, apparently, desperate cases are sometimes cured; and that limbs so shattered and wounded as to render amputation the only probable means for the preservation of life, are now and then saved. This is an uncontroverted fact, but a fact which proves very little against the common opinion; because every man of experience also knows, that such escapes are very rare, much too rare to admit of being

opinion.

ing

Theory. ing made precedents, and that the majority of such attempts fail (a).

"This consideration, relative to amputation, is of the more importance, because it most frequently requires immediate determination; every minute of delay is, in many instances, to the patient's disadvantage; and a very short space of time indeed frequently makes all the difference between probable safety and fatality. If these cases in general would admit of deliberation for two or three days, and during that time such circumstances might be expected to arise as ought necessarily to determine the surgeon in his conduct, without adding to the patient's hazard, the difference would be considerable: the former would not seem to be so precipitate in his determination as he is frequently thought to be; and the latter, being more convinced of the necessity, would submit to it with less reluctance. But, unhappily for both parties, this is seldom the case; and the first opportunity having been neglected, or not embraced, we are very frequently denied another. Here therefore the whole exertion of a man's judgment is required, that he may neither rashly and unnecessarily deprive his patient of a limb; nor, through a false tenderness or timidity, suffer him to perish, by endeavouring to preserve such limb. Some degree of address is also necessary upon such occasion, in order to convince the patient, that what seems to be determined upon hastily and with precipitation, will not safely admit of longer deliberation."

²³⁵
Of reducing a compound fracture.

The limb being thought capable of preservation, the next consideration is the reduction of the fracture. The ease or difficulty attending this depends not only on the general nature of the case, but on the particular disposition of the bone with regard to the wound.

If the bone be not protruded forth, the trouble of reducing and of placing the fracture in a good position, will be much less than if the case be otherwise; and in the case of protrusion or thrusting forth of the bone or bones, the difficulty is always in proportion to the comparative size of the wound through which such bone has passed. In a compound fracture of the leg or thigh, it is always the upper part of the broken bone which is thrust forth. If the fracture be of the transverse kind, and the wound large, a moderate degree of extension will in general easily reduce it; but if the fracture be oblique, and terminates, as it often does, in a long sharp point, this point very often makes its way through a wound no larger than just to permit such extension. In this case, the very placing the leg in a straight position, in order to make extension, obliges the wound or orifice to gird the bone tight,

Vol. X.

and make all that part of it which is out of such wound press hard on the skin of the leg underneath it. In these circumstances, all attempts for reduction in this manner will be found to be impracticable; the more the leg is stretched out, the tighter the bone will be girt by the wound, and the more it will press on the skin underneath.

Upon this occasion, it is not very unusual to have recourse to the saw, and by that means to remove a portion of the protruded bone; but this practice is frequently erroneous.

²³⁶
Of sawing off the end of a broken bone.

In some few instances, and in the case of extreme sharp-pointedness of the extremity of the bone, it may be, and undoubtedly is, right, but in many instances it is totally unnecessary.

The two most proper means of overcoming this difficulty are, change of posture of the limb, and enlargement of the wound. In many cases, the former of these, under proper conduct, will be found fully sufficient; and where it fails, the latter should always be made use of. Whoever will attend to the effect which putting the leg or thigh (having a compound fracture and protruded bone) into a straight position always produces, that is, to the manner in which the wound in such position girds the bone, and to the increased difficulty of reduction thereby induced, and will then, by changing the posture of such limb from an extended one to one moderately bent, observe the alteration thereby made in both the just-mentioned circumstances, will be satisfied of the truth of what has been said, and of the much greater degree of ease and practicability of reduction in the bent than in the extended position; that is, in the relaxed, than in the stretched state of the muscles. Reduction being found impracticable either by extension or change of posture, the obvious and necessary remedy for this difficulty is enlargement of the wound. This, to some practitioners who have not seen much of this business, appears a disagreeable circumstance: but here there is neither difficulty nor danger; it is the skin only which can require division; and in making such wound there can be no possible hazard. It is needless to say, that the division should be such as to render reduction easy; or to remind the practitioner, that such enlarged opening may serve very good future purposes, by making way for the extraction of fragments, and the discharge of matter, sloughs, &c.

²³⁷
Of enlarging the wound in the integuments.

If the bone be broken into several pieces, and any of them be either totally separated or so loose in the wound, or if they be so loosened and detached as to render their union highly improbable, all such pieces ought to be taken away; but they should be

41 Z

removed

"(a) The baron Van Swieten, writing as many others have done, that is, theoretically, on surgery, advises us, in the case of very bad compound fractures, which may most probably require amputation, to defer the operation until we have tried the force of antiseptic fomentations, and applications of like kind, for two or three days; and this opinion and advice he builds, in some measure, on the remarkable success of La Motte, in a seemingly desperate case, of a man's leg mangled by the wheel of a heavy carriage.

"That De La Motte's patient escaped I make no doubt, because he has said so: but the surgeon showed much more rashness in attempting to save such a limb, than he would have done in the amputation of it; the operation would have been the more justifiable practice.—With regard to the baron's advice, to stay two or three days, I take the liberty to add, that if you do that, stay several more; for at the end of that time (I mean two or three days) the patient will have very little chance indeed from the operation, much less than he would have had at the time of the accident.

"I should be very sorry to be thought a patron or an adviser of rashness or cruelty; but in what I have here said, I believe I shall have every man in the profession, who has either true humanity, or sound judgment founded on experience, on my side."

Theory.

removed with all possible gentleness, without pain, violence, or laceration; without the risk of hæmorrhagy; and with as little poking into the wound as possible. If the extremities of the bone be broken into sharp points, which points wound and irritate the surrounding parts, they must be removed also. But the whole of this part of the treatment of a compound fracture should be executed with great caution. The objects of fear and apprehension in a compound fracture (that is, in the first or early state of it) are, pain, irritation, and inflammation: these are to be avoided, prevented, and appeased, by all possible means, let every thing else be as it may: and altho' certain things are always recited as necessary to be done, such as removal of fragments of bone, of foreign bodies, &c. &c. yet it is always to be understood, that such acts may be performed without prejudicial or great violence, and without adding at all to the risk or hazard necessarily incurred by the disease.

238
Of dislocations.

In dislocations of the joints, as well as in fractures of the bones, our great attention ought to be paid to the muscles belonging to the part affected. Tho' their action is regular and just, when the bone to which they are attached comes to be displaced, they pull and distort the limb in many different ways; and from them only arises the great difficulty in reducing luxated joints. From this consideration, Mr Pott lays down the following maxims with regard to luxated joints:

"1. Although a joint may have been luxated by means of considerable violence, it does by no means follow that the same degree of violence is necessary for its reduction.

"2. When a joint has been luxated, at least one of the bones of which it is composed is detained in that its unnatural situation, by the action of some of the muscular parts in connection with it; which action, by the immobility of the joint, becomes as it were tonic, and is not under the direction of the will of the patient.

"3. That the mere burial ligaments of some of the joints, endued with great mobility, are weak, distractile, and constantly moistened: that, for these reasons, they are capable of suffering considerable violence without being lacerated; but that they are also sometimes most certainly torn.

"4. That did the laceration of the said ligaments happen much more frequently than I believe it does, yet it cannot be a matter of very great consequence, as it neither totally prevents reduction, when timely and properly attempted, nor a consequent cure (c).

"5. That supposing such accident to be frequent, yet as it is impossible to know, with any kind of certainty, whether it has happened or not, or in what part of the ligament, it cannot be admitted as a rule for our conduct, nor ought such mere conjecture to produce any deviation from what we ought to do were there no such supposition. Could we know with cer-

tainty when and where this had happened, very useful information might indeed be drawn from it.

"6. That all the force used in reducing a luxated bone, be it more or less, be it by hands, towels, ligatures, or machines, ought always to be applied to the other extremity of the said bone, and as much as possible to that only.

"7. That in the reduction of such joints as are composed of a round head received into a socket, such as those of the shoulder and hip, the whole body should be kept as steady as possible, for the same reason as in the foregoing.

"8. That in order to make use of an extending force with all possible advantage, and to excite thereby the least pain and inconvenience, it is necessary that all parts serving to the motion of the dislocated joint, or in any degree connected with it, be put into such a state as to give the smallest possible degree of resistance.

"9. That in the reduction of such joints as consist of a round head moving in an acetabulum or socket, no attempt ought to be made for replacing the said head until it has by extension been brought forth from the place where it is, and nearly to a level with the said socket.

"10. The last principle which I shall take the liberty to mention, and which I would inculcate very seriously, is, that whatever kind or degree of force may be found necessary for the reduction of a luxated joint, that such force be employed gradually; that the lesser degree be always first tried, and that it be increased gradatim."

SECT. IV. Of Abscesses and large Suppurations.

Under the article *MEDICINE*, n° 154. it has been observed, that one of the ways in which inflammation terminates is by suppuration; in which case an *abscess* is formed. This takes place in consequence of that part of the body which was inflamed being rendered impervious to the circulating fluids; whence they are at last melted down, and converted into what is called *pus* or *matter*.—That an inflammation will terminate in an abscess, may be known from the length of time it has continued, from the remission of the pain and hardness, the greater elevation of the skin in the middle part, a change of colour from red to bluish or livid, a slight fever with shivering, and from a fluctuation of matter perceived on handling the part.

During the first stage of the inflammation, however, we ought, for the most part, to endeavour to resolve it, or prevent the formation of an abscess. Yet some cases must be excepted. For instance, those inflammatory swellings which sometimes occur in fevers, or succeed to them, ought always to be brought to suppuration; and it might be very dangerous to attempt a resolution of them. In swellings of a seropulous nature, it is perhaps best to do nothing at all, either

(c) In the accident of a dislocated tibia from a broken fibula, the strong, inelastic, tendinous ligaments, which fasten the end of the former bone to the astragalus and os calcis, are frequently torn; and as these, by proper care, almost always do well, and recover all their strength, there is the greatest reason to expect, that the more weak distractile ones do the same. The only mischief which seems most likely to follow from a laceration of the latter, is from an effusion of the synovia; of which, Mr Pott thinks, he has seen an instance in the joint of the ankle. That the laceration of the burial ligament of the shoulder cannot be a frequent or general impediment to reduction, appears from his never having, in more than 20 years care of an hospital, met with a single instance of its impracticability, when attempted in time.

239
In what cases we might attempt the resolution of an inflammation

Theory.

Theory.

either with a view to resolve or suppurate. Thus it might be dangerous to make use of repellant applications, at the same time that it is by no means advisable to promote their suppuration; the cure of such swellings, when opened, proving always very troublesome; while at the same time it is known, that such swellings may remain for a very long time without any risk to the patient. In the lues venerea, too, as we are possessed of a certain antidote for the disorder, it is best not to attempt the suppuration of any buboes which may appear; as the cure of them, when opened, very often proves extremely troublesome; and as their being opened cannot contribute any thing towards their cure.

Where the inflammation is but beginning, and the symptoms are not so violent as to affect the general system, topical remedies, with a due attention to regimen, often answer in resolving them. But when the inflammation runs high, with general symptoms of fever, it then becomes necessary to pay attention to these at the same time. Warm fomentations and cataplasms have generally been recommended for all inflamed parts: but these have a great tendency to promote suppuration, and are therefore very improper while the inflammation may be supposed capable of resolution. The first thing, therefore, to be attended to in the case of every inflammation, is the removal of the exciting causes, which either have brought it on originally, or which may continue it after it is begun. Such are extraneous bodies in wounds, pieces of fractured bones, luxations, &c. with whatever else may have had a tendency to foment and keep up the disease. Of all the various applications for an inflamed part, those of a sedative nature are chiefly to be depended upon; and, next to these, emollients. Of the former kind we may consider all the different preparations of lead dissolved in vinegar; together with the vegetable acid itself, which generally acts also as a sedative. Among the latter we may place, in the first class, the mild expressed oils, as also the soft ointments made with these oils and pure wax.

When we speak of sedative medicines, however, it must not be understood that all of that class are to be used indiscriminately. Thus opium, though one of the most powerful of all sedatives, yet as its application, externally, to the human body, is always attended with some degree of irritation, however useful it may at times be found in some particular species of inflammatory disorders, will never, probably, as an external application, become of general use in these cases. Warm emollient fomentations, too, though powerful sedatives, as tending more effectually to remove tension and pain than perhaps any other remedy, yet are constantly found to be improper where a resolution is to be wished for, as we have already observed. Their constant effect is, either to bring the swelling to a suppuration, or to relax the parts in such a manner as to render the removal of the disorder always exceedingly tedious.

Mr Bell recommends the preparations of lead as the proper applications, in cases of external inflammation, where we wish for a resolution. These medicines have lately drawn the attention of the public by the great encomiums passed upon them by M. Goulard, who thus endeavoured to pass off one of his own compositions

under the very improper name of *extract of lead*. This medicine, which at best can only be a saturated solution of lead in strong vinegar, Mr Bell justly observes, has not the advantages of saccharum saturni. "For (says he) although in the *Extrait de Saturn* of Goulard, as likewise in the *Acetum Lithargiræ* of our dispensatories, which are both, it may be observed, very nearly the same, we may be very certain of the quantity of lead employed to the vinegar; yet we can never, but by crystallization, know exactly, or even nearly, how much of the former the menstruum may have dissolved, as that must depend on a variety of accidents; and particularly on the strength of the acid and exact degree of heat employed; which are circumstances we have not always in our power exactly to regulate. For these reasons, therefore, the salt or sugar of lead, as it is called, should, for external use, be always preferred." The best method of applying it, he says, is in the form of a watery solution; and he gives the following formula: "℞. Sacchar. saturni. ʒiſs. solve in acet. pur. ʒiv. et adde aq. fontan. destillat. ℥ij."

The addition of vinegar renders the solution much more complete than it otherwise would be; and without it, indeed, a very considerable proportion of the lead generally separates and falls to the bottom.

In making use of this solution in cases of inflammation, as it is of consequence to have the parts affected kept constantly moist with it, cataplasms prepared with it and crumb of bread, in general answer that intention exceedingly well. But when the inflamed part is so tender and painful as not easily to bear the weight of a poultice, which is frequently the case, pieces of soft linen moistened with the solution answer the purpose tolerably well; although, when there is not that objection to the use of cataplasms, as they retain the moisture longer, they should always be preferred. But whichever of the two are had recourse to, they should always be applied cold, or at least with no greater warmth than is merely necessary for preventing pain or uneasiness to the patient: they should be kept almost constantly at the part, and renewed always before turning stiff or hard.

Among the remedies recommended for external use, Of emollients in cases of inflammation, were mentioned emollients, &c.

These, when the tension and irritation on the skin are considerable, are often attended with very great advantage: the parts affected being, in such a state of the disorder, gently rubbed over with any of the mild expressed oils two or three times a-day, the tension, irritation, and pain, are often very much relieved, and the discussion of the tumour thereby greatly promoted.

In every case of inflammation, indeed, emollient applications would afford some relief. But as the preparations of lead, already recommended, prove, in all such disorders, still more advantageous; and as unguents of every kind tend considerably to blunt the action of lead; these two sets of remedies should as seldom as possible be allowed to interfere with one another: and emollients should accordingly never be prescribed, but when the circumstances already mentioned, of irritation, tension, and pain, are so considerable as to render their application altogether necessary.

240
The applications proper for inflammation.

241
Of the preparations of lead.

Theory.

Theory.

Unctuous substances have, too, been condemned in such cases upon a different principle, as tending to stop the pores, and consequently to obstruct the perspiration of those parts to which they are applied. It is not, however, probable, that in this way they could prove very hurtful in preventing the resolution of inflammation; which must always, it is imagined, be effected in a very different manner than by perspiration.

243
Of the method of using the vegetable acid.

When the part affected with inflammation is very tender, or lies deep, applications of the vegetable acid are then often had recourse to with considerable advantage; and the most effectual form of using it seems to be by way of cataplasm, made with the strongest vinegar and crumb of bread. In such cases, too, an alternate use of this remedy, with the saturnine solution, has produced more beneficial effects than are commonly observed from a continued course of any one of them.

At the same time that these applications are continued, bleeding with leeches, or cupping and scarifying, as near as possible to the part affected, is generally of very great service; and in no case of local inflammation should ever be omitted. In all such cases, the whole body, but more especially the diseased part, should be preserved as free as possible from every kind of motion; and, for the same reason, the necessity of a low cooling diet, in every inflammatory disorder, appears obvious, as does also a total abstinence from spirituous and fermented liquors.

244
Of blood-letting and other evacuations.

In slight cases of inflammation, a due perseverance in the several articles taken notice of, will, in general, be found sufficient for every purpose. But when there is likewise a full, hard, or quick pulse, with other symptoms of fever, general blood-letting becomes then always necessary; the quantity of blood taken away being always to be determined by the violence of the disorder, and by the age and strength of the patient. The use of gentle laxatives, too, together with cooling diaphoretic medicines, are always attended with very good effects.

These different evacuations being premised, the next object of consequence is to procure ease and quietness to the patient; which is often, in inflammatory cases, of more real service than any other circumstance whatever. The most effectual remedy for this purpose is opium; which, when pain and irritation are considerable, as in extensive inflammations very frequently happens, should never be omitted. In large wounds, especially after amputations and other capital operations, in punctures of all kinds, too, large doses of opium are always attended with remarkable good effects. In all such cases, however, opium, in order to have a proper influence, should, as was observed, be administered in very large doses: otherwise, instead of proving serviceable, it seems rather to have the contrary effect; a circumstance which is, perhaps, the chief reason for opiates in general having been very unjustly condemned in every case of inflammation.

By a proper attention to the different circumstances taken notice of, in the course of three or four days, and sometimes in a shorter space of time, resolution of the tumour will in general begin to take place; at least before the end of that period, it may, for the most part, be known how the disorder is to terminate.

If the heat, pain, and other attending symptoms, abate, and especially if the tumour begins to decrease, without the occurrence of any gangrenous appearances, we may then be almost certain that by a continuance of the same plan a total resolution will in time be effected.

But, on the contrary, if all the different symptoms rather increase; and especially, if the tumour turns larger, and somewhat soft, with an increase of throbbing pain; we may then, with tolerable certainty, conclude that suppuration will take place; and should therefore immediately desist from such applications as were judged proper while a cure was thought practicable by resolution, and endeavour to assist nature as much as possible in the formation of pus, or what is called *maturation* of the tumour.

For this reason, in every case of inflammation, the different evacuations, especially that of blood-letting, which may have been advisable while the swelling was attempted to be dissipated, should never be carried a greater length than may be merely necessary for moderating the febrile symptoms: for by reducing the system too much, and a suppuration afterwards taking place, its progress in that case becomes always much more slow and uncertain than it would have been had a due attention been paid to these evacuations; nor will the patient be afterwards so able to bear, especially if it is considerable, the discharge that must necessarily ensue from opening the abscess.

Although it was remarked above, that if in general, in the course of three or four days, there does not some appearance of resolution occur, that suppuration will most probably take place, and that consequently a change of treatment becomes necessary; yet this, it must be observed, is only to be taken in a limited sense: for the time of desisting from one mode of treatment and commencing the other, must always depend very much on the seat of the inflammation; such disorders being, in some parts, much more apt to terminate in a speedy suppuration than in others.

Thus, in the cellular membrane, and in different soft parts, inflammatory disorders of all kinds terminate much more readily and quickly than when any of the tough membranous parts are affected. Hence, in the coats of the eye and of the testicles, very violent inflammations often continue for many days, nay, even for weeks, without either abating in the symptoms or ending in suppuration. In such cases, therefore, which go on even to a very considerable length, we need not be afraid of continuing the discutient applications for a much longer time than would in general be otherwise proper: we should never therefore be deterred from using them, unless either an evident suppuration has taken place, or there appears, from the violence of the symptoms, a certain risk either of gangrene or of some incurable obstruction; in which event, we are, no doubt, always to endeavour to procure the suppuration of the tumour.

When the means used for discussing or resolving an inflamed tumour have proved ineffectual, the next attempt of the surgeon ought to be to bring it to maturity as soon as possible; and for this purpose there is nothing better than to preserve a proper degree of heat in the parts. The method commonly had recourse

245
Of bringing a tumour to suppuration.

Theory.

Theory.

course for the application of heat to an inflamed part, is by the means of warm fomentations and cataplasms; and when these are regularly and frequently renewed, nothing, it is probable, could more effectually answer the purpose. But in the ordinary manner in which they are applied, by the cataplasms being renewed only once, or at most twice a day, they must always, it is imagined, do more harm than good. For so soon as the degree of heat they were at first possessed of is dissipated, the moisture kept up by them, with the consequent evaporation that ensues, must always render the part a great deal colder than if it had been merely wrapped in flannel without the use of any such application.

In order to receive all the advantages of such remedies, the part affected should be well fomented with flannels pressed out of any warm emollient decoction, applied as warm as the patient can easily bear them, continued at least half an hour at once, and repeated four times a day.

Immediately after the fomentation is over, a large emollient poultice should likewise be applied warm, and renewed every second or third hour at farthest. Of all the forms recommended for emollient cataplasms, a common milk-and-bread poultice, with a proportion of butter or oil, is perhaps the most eligible; as it not only possesses all the advantages of the others, but can at all times be more easily obtained.

Roasted onions, garlic, and other acrid substances, are frequently made use of as additions to maturing cataplasms. When there is not a due degree of inflammation in the tumour, and when it appears probable that the suppuration would be quickened by having the inflammatory symptoms somewhat increased, the addition of such substances may then be of service; but when stimulants are necessary in such cases, a small proportion of strained galbanum, or of any of the warm gums, dissolved in the yolk of an egg, and added to the poultices, is not only a more elegant, but a more certain form of applying them.

Whenever the inflammation, however, takes place to a proper degree, such stimulating substances never can be necessary; and in many cases, it is apprehended, they may even do mischief.

In such tumours as, from their being possessed of little or no inflammation, are commonly said to be of a cold nature, as they are generally indolent, and proceed very slowly to suppuration, plasters composed of the warm gums are often had recourse to with considerable advantage. In such cases, they are not only of use by the stimulus and irritation they occasion, but by the heat which they tend to preserve in the part. They become particularly necessary when the patient, by being obliged to go abroad, cannot have cataplasms frequently enough renewed, or so conveniently applied; but when some such objection does not occur, the latter, for very obvious reasons, should always be preferred.

Dry cupping, as it is termed, that is, cupping without the use of the scarificator, upon or as near as possible to the part affected, is frequently had recourse to with advantage in promoting the suppuration of tumours. It is only, however, in such as these last mentioned, where there seems to be a deficiency of inflammation, that it can ever either be necessary or

useful; but in all tumours of a real indolent nature, and where there is still some probability of a suppuration being effected, I have seldom observed such effects from any other remedy.

These different applications, under the restrictions taken notice of, being continued for a longer or shorter time, according to the size of the tumour, its situation, and other circumstances, a thorough suppuration may in general at last be expected.

Matter being fully formed in a tumour, is known by a remission of all the symptoms taking place: the dolor pulsatilis, that before was frequent, now goes off, and the patient complains of a more dull, constant, heavy pain: the tumour points at some particular part, generally near to its middle; where, if the matter is not encephaloid, or deep seated, a whitish yellow appearance is observed, instead of a deep red that formerly took place; and a fluctuation of a fluid underneath, is, upon pressure, very evidently discovered. Sometimes, indeed, when an abscess is thickly covered with muscular and other parts; and when, from concurring circumstances, there can be little doubt of there being even a very considerable collection of matter; yet the fluctuation cannot be readily distinguished: but it does not often happen, that matter is so very deeply lodged as not to be discovered upon proper examination.

This, however, is a circumstance of the greatest consequence in practice; and deserves, it may be remarked, more attention than is commonly given to it. In no part of the surgeon's employment, is experience in former similar cases of greater use to him than in the present; and however little it may appear, yet nothing, it is certain, more readily distinguishes a man of observation and extensive practice, than his being able easily to detect collections of deep-seated matter; whilst nothing, on the contrary, so materially affects the character of a surgeon, as his having, in such cases, given an inaccurate or unjust prognosis; as the event, in disorders of that nature, comes generally at last to be clearly demonstrated to all concerned.

Together with the several local symptoms of the presence of pus, already enumerated, may be mentioned the frequent shiverings that patients are liable to on its first formation: these, however, seldom occur so as to be distinctly observed, unless the collection is considerable, or seated internally in some of the viscera.

After the matter is fully formed, and the abscess brought to maturity, the only remedy is to open it, and give vent to the pus it contains. In many cases, indeed, nature will do the work, and abscesses when superficially seated will certainly burst of themselves; but where the matter lies deep, we are by no means to wait for this spontaneous opening; as the pus will acquire an acrimony, before it can break through the integuments, which may prove very prejudicial to health. However, it is a general rule not to open abscesses till a thorough suppuration has taken place; for, when laid open long before that period, and while any considerable hardness remains, they commonly prove more troublesome, and seldom heal so kindly.

In some cases, however, it is necessary to deviate from this general rule, and to open them a good deal sooner; particularly in all such critical abscesses as occur

occur in malignant fevers. In the plague, too, we are commonly advised to open such tumours, so soon as they are at all tolerably advanced, and not to wait till they are fully matured; as, from experience in these disorders, it is found to be of more consequence, for the removal of the original disease, to have a quick discharge of matter produced, than any harm the patient can ever suffer from having a swelling somewhat prematurely laid open.

In abscesses, too, situated on any of the joints, or upon either of the large cavities of the breast and abdomen, and more especially when they seem to run deep, they should always be opened as soon as the least fluctuation of matter is discovered. For, when the resistance is on every side equal, they just as readily point internally as outwardly: and the consequence of a large abscess bursting into either of the large cavities especially, is well known most frequently to prove fatal: An instance of which, in the following case, with very little attention, might have been prevented.

249
Case of an
abscess
breaking in-
wardly.

A surgeon of eminence, and of very extensive practice, was applied to by a young healthy-looking man, with a large abscess upon the left side of his chest. A fluctuation of a fluid was, upon pressure, very evidently discovered; and it was agreed, by other two practitioners that were present, that an opening should be made to give vent to the matter. But the operator, being much engaged in business, could not fix on an earlier period for doing it than the third day from the patient's applying to him: unluckily, however, the patient died suddenly in his bed the night before the abscess was to have been opened.

On examining the body, the tumour had disappeared entirely, without any external opening being observable; and, on opening the thorax, it was found to have burst inwardly upon the lungs, and so had produced immediate suffocation.

In every other circumstance, however, except in the cases alluded to, the rule in opening abscesses, is, as was already remarked, To allow a thorough suppuration to take place, before any vent whatever be given to the matter; and it being then determined to lay the collection open, the next question that occurs, is with respect to the manner of doing it. But the consideration of this belongs to the next Part.

250
Of white
swelling.

Under the head of *abscesses*, we may reckon those tumours of the joints usually called *white swellings*; for though they never suppurate in such a kindly manner as the common abscess, yet they certainly contain collections of a kind of pus as much as the former.—The only regular treatise which has yet appeared on white-swellings is that of Mr Bell surgeon in Edinburgh. He observes, that there are two species of the disease; the one of a mild nature, and frequently admitting of a cure; which the other never does. The former, named by our author the *rheumatic* species of white swelling, begins with an acute pain, seemingly diffused over the whole joint, and frequently extending along the tendinous aponeuroses of the muscles which communicate with it. There is, from the beginning, an uniform swelling of the whole surrounding integuments; which in different patients is in different degrees, but always sufficient to occasion an evident disparity between the size of the diseased joint and the other. Great tension generally prevails; but

251
Of the
rheumatic
white swell-
ing.

in this period of the disorder there is seldom any external change of colour. From the commencement of the disease, the motion of the joint is attended with exquisite pain, and the patient keeps it constantly in a relaxed posture, finding that the easiest. Hence the tendons become extremely stiff and rigid, till at last the joints have the appearance of complete and real anchyloses. The swelling now begins to augment, till the joint has acquired three or four times its natural size: the cuticular veins become turgid and varicose; at the same time that the muscular substance of the limb below decays, though it frequently acquires an equality in size by becoming oedematous: the pain becomes intolerable, especially when the person is warm in bed or otherwise heated: abscesses form in different parts, which, either breaking of themselves, or by being laid open, discharge considerable quantities of matter, but without any remarkable effect in reducing the size of the swelling. The pus discharged from these is at first of a tolerably good consistency, but soon degenerates into a thin ill-conditioned sanies. However, the orifices from whence it flows soon heal up, unless they are kept open by art; and new collections breaking out, they burst and heal up as before; so that in long-continued disorders of this kind, the surrounding integuments are often entirely covered with cicatrices.

In the mean time the health of the patient gradually declines; first from the violence of the pain, which often deprives him of sleep and appetite; and then from the absorption of matter into the system, which always certainly takes place in some degree from its first formation in the different abscesses; but which indeed never appear so evidently till the different abscesses have been laid open; after which a quick pulse, night-sweats, and a weakening diarrhoea, are sure to occur, and which generally carry off the patient, if the member is not either amputated, or the disease cured some other way.

On dissection limbs which have been amputated for white swellings, the original disease appears to have ances on been a morbid thickening of the surrounding liga- dissection the limbs amputated for this species of white swelling.

ments, without any other affection of the joint whatever; the bones and cartilages always remaining perfectly sound, as likewise the synovia both in quantity and consistence. In some instances where the disease has been very violent, this thickness of the ligaments appears to have increased much more than in others where it was more mild. But in the more advanced stages of the disorder, when abscesses have formed in different parts, when the pain has been long very violent, with great addition of swelling, the thickness of the ligaments is then more considerable, and is generally, if not always, attended with an effusion, into the surrounding cellular substance, of a thick glairy matter, which gives to swellings of this kind an elastic springy feel, independent of the collections of matter above-mentioned, the fluctuation of which may also be perceived. Through this glairy matter the collections of pus are found to run in various directions, without seeming, however, to mix with it. In some instances a great many small hydatides are observed along with the collections of matter; all which form a confused mass, incapable of further dissection.

All the above-mentioned appearances have been observed

Theory. served without any affection of the bones or cartilages. But when, by a very long continuance of the disorder the ligaments come to be corroded by the different collections of matter, the cartilages then, and in consequence thereof the bones, soon begin to suffer. The tendons of the flexor muscles, though very stiff and contracted, do not, upon dissection, show any signs of disease.

²⁵³ Of the serophulous white swelling. The above is an history of the most mild species of the serophulous white swelling; the more inveterate kind our author names the *serophulous white swelling*. In this the pain is commonly very violent; more acute than in the former; and, instead of being diffused, is confined to a particular spot, commonly the very middle of the joint; so that patients will sometimes say they could cover the whole pained part with a crown-piece or less. The swelling also is commonly inconsiderable at first; inasmuch that, on some occasions, even when the pain has been very violent, little difference in point of size could be observed between the diseased joint and the sound one of the opposite side. Here also the motion of the joint is attended with very great pain, and the tendons become stiff, for the same reason as in the former. As the disorder advances, the pain becomes more violent, and the swelling increases, with an evident enlargement of the ends of the bones composing the joints. The same elastic feel, together with similar abscesses, occur in this as in the last: but upon opening them they commonly discharge a thin fetid stuff; the bones are found to be carious, and pieces of them are frequently discharged at the openings.

On the farther continuance of the disorder, the constitution comes here likewise to suffer as in the first species of the disease; and a diarrhoea with night-sweats commencing, the patient is soon reduced, from perhaps the fullest habit, to little more than skin and bone.

²⁵⁴ Apperances on dissectiong the amputated limbs. Upon such joints being dissected, either after death, or after amputation of the member in the first stages of the disorder, the soft parts seem very little affected: but in all, even the very slightest cases, there is constantly observed an enlargement either of the whole ends of the bones, or of their epiphyses; frequently of those on one side of the joint only; in others, again, the bones on both sides have been affected.

This enlargement sometimes occurs without any other evident disease: but in general, and always in a more advanced state of the complaint, the soft spongy parts of such bones appear dissolved into a thin, fluid, fetid matter; and that too, in some cases, without the cartilages which surround them seeming much affected. In process of time, however, the cartilages come likewise to be dissolved; and then the different matter, viz. that of the bones and softer parts, all mixing together, such swellings being in that state laid open, exhibit a still more confused collection than is generally observed even in the worst stages of the other species of the disorder.

Although it was remarked, that in the early periods of the complaint, the surrounding soft parts do not always appear much affected; yet, in its farther progress, they likewise are always brought to suffer. The ligaments become thickened, and the contiguous cellular membrane stuffed with that viscid glairy kind

of matter as observed in the other species of the disorder.

Having thus given a particular account of the different appearances generally observed in both species of white swelling, we come now, in course, to the consideration of the different causes which tend to produce them. That the ligaments of the joints only are first affected in this disorder, is from the history of the dissections rendered evident; they, in the first stages of the complaint, being almost the only parts that are found diseased. The effusions, into the cellular membrane, of that thick glairy matter taken notice of, are probably occasioned by an exudation from the vessels of those ligaments that have been originally inflamed, it being known that such parts never furnish a proper fluid for the formation of purulent matter: In the course of the disease, indeed, abscesses containing real pus do always appear; but never till inflammation has been communicated to the surrounding parts, which more readily afford a fluid proper for that purpose.

Upon the whole, therefore, we may conclude, that the first species of white swelling is always occasioned by an *inflammatory or rheumatic affection* of the ligaments of such joints as it attacks, and that too from whatever cause such inflammation may originally have proceeded.

The other species of the disorder, from all the symptoms enumerated, and from the appearances on dissection, seems evidently to be originally an affection of the bones; the surrounding soft parts coming only to suffer in the progress of the disease, from their connection with and vicinity to these.

This last species of white swelling very seldom occurs as the consequence of any external accident; generally beginning without the patient being in the least able to account for it: And from the effects which it usually produces on the bones attacked, it would appear to be a species of the real *spina ventosa*; and which again is very probably a disease of the same nature in the bones, as serophula is of the soft parts. Indeed, the appearances of the two disorders, after making allowance for their different situations, are exceedingly similar: they both begin with considerable enlargements or swellings of the parts they invade; which afterwards in both, too, generally end in evident ulcerations; and they both likewise frequently occur in the same person and at the same time.

It is likewise observed, that this species of white swelling is generally either attended with other evident symptoms of serophula subsisting at the time; or that the patient in an early period of life has been subject to that disease; or, what is nearly the same, that he is descended from serophulous parents, and consequently most probably has the seeds of that disease lurking in his constitution.

From all these circumstances, it may with probability be concluded, that this species of white swelling is commonly, if not always, of a serophulous nature: and it having already been shown, that the other species of the disorder is to be considered as an inflammatory, or what we have termed a *rheumatic*, affection; and a thorough distinction of the two different species being, in the treatment, a matter of very great importance; it will not here be improper to

give

²⁵⁵ Causes of white swelling. Theory.

Theory.

give a short enumeration of the several diagnostic or most characteristic symptoms of each.

256
Diagnostics
of the dif-
ferent
species of
the disease.

The pain in the white swelling from a rheumatic disposition is, as was formerly remarked, always, from the beginning, diffused over the whole joint, and on some occasions extends even a considerable way along the muscles that are attached to it; whereas, in the other species of the disorder, the pain is not only always at first, but sometimes even when the complaint has been of considerable standing, confined to a very small circumscribed space.

In the former, the swelling is always confined to the soft parts, and is from the beginning exceedingly evident; but in the latter, there is seldom for some time any perceptible swelling; and when it does more sensibly appear, the bones are found evidently to be the parts chiefly affected, the surrounding teguments coming only to offer on a farther progress of the disease.

These are the chief local differences of the two species of this disorder; but some assistance in the distinction may likewise be obtained, from the general habit of the patient, and from the manner in which the complaint may seem to have been produced.

Thus, when such swellings occur in young, strong, plethoric people, especially in such as have formerly been subject to rheumatism, and that whether in consequence of an immediate external accident or not, such, most probably, will always prove to be of the mildest or rheumatic species of the disorder.

Whereas, when swellings of this nature appear in such patients as are otherwise evidently of scrophulous dispositions; where, together with a fine skin and delicate complexion, there are either, on examination, found hardened glands in the neck, arm-pits, or inguina; or it is discovered that the patient has, from his ancestors, a title to such complaints; when either any or all of these circumstances occur, and if the disorder has begun in the manner formerly described, without any evident external cause, we need be under very little doubt in concluding it to be of a scrophulous nature.

The great utility of properly distinguishing the two different species of white swellings, appears in no circumstance so evident as in the treatment. In the one, there being some chance, by proper remedies, of being serviceable to the patient; whereas in the other, *viz.* the scrophulous, it is not probable that art will ever be able to afford much assistance.

In the rheumatic white swelling, as it is always at first evidently of an inflammatory nature, considerable advantages are commonly obtained by a due attention to a proper antiphlogistic course.

257
Method of
cure in the
rheumatic
white swelling.

The first remedy which, with this view, should be put in practice, is blood-letting; but instead of general evacuations from the arm or elsewhere, it proves always more effectual to take the blood immediately from the part affected. Cupping and scarifying is here a principal remedy. The instrument should be applied to each side of the diseased joint; on each side of the rotula, for instance, when the knee is the part affected, and at least eight or ten ounces of blood discharged; and this to be repeated at proper intervals, once, twice, or oftener, according to the violence of the symptoms and state of the patient's strength at the time.

Theory.

In the ordinary way of discharging only an ounce or two of blood by this operation, it has in general very little or no influence; but in the quantities mentioned, and which, by those accustomed to the practice, is commonly easily obtained, it most frequently is attended with very considerable effects.

It must here be observed, that cupping is, in these cases, much superior to leeches; which is not only a more tedious method of getting the same quantity of blood, but the swelling occasioned by the application of any considerable number of these animals proves frequently very troublesome; and, what is often of worse consequences, gives sometimes an interruption, for a time, to the use of other remedies.

Upon the anterior part of the joint, where the cupping-glasses have not been placed, a small blister should be directly applied, and the part kept open with issue-ointment, till the wounds from the scarificator are so far healed, that a vesicatory may likewise be laid on one side of the joint; and so soon as that is nearly healed, the other side should be also blistered.

By thus alternately applying them, first to the one side, and then to the other, almost a constant stimulus is kept up; which, in deep-seated inflammations, seems to have fully a greater influence than all the discharge occasioned by blisters.

Gentle cooling laxatives at proper intervals are here of use too; and the patient should, in every respect, be kept upon a strict antiphlogistic course, both as to diet and every other circumstance. From a due attention to which, with a continuance of the topical treatment already recommended, considerable advantages have frequently been observed, more indeed than from any other remedies ever used in this complaint.

It is in the first stages only, however, of the disease, that such a course can probably be of much service; and in such it has frequently been a means of curing disorders, which otherwise would probably have proceeded to the last stages of white swellings.

The original inflammatory affection being once over, these sort of drains seem to have little or no influence, and ought not then to be long persisted in, as tending to prevent the use of other remedies, which, in an advanced state of the disease, prove commonly more efficacious.

The inflammation being mostly gone, and while there are yet no appearances of the formation of mat-
258
When mer-
cury is use-
ful.

ter, mercury, in these circumstances, has sometimes been known of use; not given so as to salivate, but merely to affect the mouth gently, and to keep it somewhat sore for a few weeks.

The best form of using mercury, in such cases, is certainly by way of unction; as it allows, at the same time, of the application of friction; which, in all such swellings, may of itself be in some measure considered as a remedy. For this purpose, an ointment of quicksilver and hog's lard should be prepared; but with so small a proportion of the former, that the patient may admit of two drams of the ointment being rubbed in three times a-day. In order to rub that quantity of the medicine in with gentle friction, an hour each time is at least necessary, and which is as little as should ever be given in order to receive all the advantages that attend the practice: for however useful friction, in

Theory. in such cases, may be, when properly applied, in the ordinary way of continuing the remedy for a few minutes only, it is not probable it can ever have much influence.

Gentle mercurials, given internally, are here sometimes of service too; but as all the advantages to be derived from them in that form are obtained from the union, together with that of the friction necessary for its application, the latter, in all such cases, should certainly be preferred.

By Le Dran, and other French writers, falls of warm water on swellings of this nature are much recommended; and there is no sort of doubt, but a long-continued and reiterated application of that remedy may, in the first stages of such complaints, be often attended with very good effects.

259
A stiffness of the joint sometimes remains after white-swellings.

By a proper use of these different applications, *viz.* of the several topical remedies in the first or inflammatory state of the disease, and afterwards (still, however, before the formation of matter) of mercurials, friction, &c. many affections of this nature have been entirely removed. But in many instances, when, either by the use of medicines, or by an effort of nature, the swelling and pain are almost entirely, or even wholly removed, it frequently happens, by the bent position the limb has been for a long time kept in, that the use of the joint comes to be entirely lost, having often acquired such a degree of stiffness, that any attempts to move it are commonly attended with very great pain.

260
Mistakes concerning stiffness of the joints.

Unluckily, in all such cases, these affections of the joints have been constantly attributed to one or other of two different causes, which are both in their nature incurable, *viz.* either to the ends of such bones as compose the joints having run into one another, so as to become firmly conjoined in consequence of the surrounding cartilages being abraded; or to the inspissation, as it is termed, of the synovia of the joints, whereby their cavities are supposed to be entirely filled up, and no space thereby left for the future motion of the different bones.

261
Mr Bell's opinion.

"Both these opinions, however, (says Mr Bell), I can, from a great number of facts, assert to be in general at least very ill founded: for although, by an abrasion of the cartilages which surround the different bones at the joints, an union of their extremities may very readily be occasioned, and is no doubt on some occasions the cause of such affections; yet from a variety of diffusions, I am convinced that it is an exceeding rare occurrence, and, in cases of white swelling, never happens but in the most advanced stages of the disorder: the only causes almost of the stiffness of the joints, in such cases, being that contracted state of the flexor tendons, formerly taken notice of in the description; at least, in nineteen cases out of twenty, it probably is so.

"There is nothing indeed more deceiving than the feel on such occasions: for when the disorder has been of long standing, the stiffness and immobility are generally so considerable, as, at first sight, always to appear as if a real conjunction of the bones certainly subsisted; many instances of which I have known, that had been all along considered as real anchylosis of the joint kind; but which, on dissection, were constantly

found to proceed merely from a contracted state of the flexor muscles and tendons.

"With respect to the other opinion, which did formerly so universally, and with many still does, prevail, of such affections generally proceeding from an inspissated state of the synovial fluid, it has for some time, by many anatomists, been much doubted if it ever occurs; and from all the opportunities I have had of dissecting such diseased joints, I am pretty much convinced, that it either never does take place, or at least that it is an exceeding rare occurrence: for in every case of this kind, even when the disease had been of very long continuance, if the capsular ligament of the joint remained undivided, so that no matter from the surrounding soft parts got admittance, and when the ends of the bones were not become carious, the synovia always retained its natural appearances both in colour and consistence. So that it is very probable, the many causes of diseased joints, attributed to affections of that fluid, have been more founded on mere hypotheses than on facts and experience.

"This stiffness of the joint, therefore, which to a certain degree always occurs in white swellings, proceeding seldom or never from either of the causes mentioned, which might probably both be considered as incurable, but merely from a preternatural contraction of the muscles and tendons, we have from that circumstance great reason to expect, that in many situations a good deal may be done towards its removal. And in fact, there is no sort of doubt but complaints of this kind, which often remain after every other symptom of white swelling has disappeared, may, on many occasions, be got the better of, merely by a long-continued use of emollients: several instances, indeed, of this I have seen, some of which had been thought to be of the worst species of anchylosis.

"The best, and probably least offensive, emollient that can be used, is pure olive oil applied warm; as much of it as can be easily rubbed in by an hour's gentle friction should be regularly done at least three times a-day; and instead of confining the friction altogether to the rigid tendons, as is commonly done, it should be extended over the whole muscles, even to the insertions of their other extremities; but more especially on their fleshy muscular parts, where the principal cause of the continuance of such complaints is probably seated; these parts being chiefly, if not altogether, possessed of the contractile, and consequently of the resisting, powers.

"I have known used, too, in this complaint, as *Neat's-foot oil* some-what inferior, an emollient, and often with advantage, an oil extracted from animal-substances, known by the name of *neats foot oil*: but as it is more apt to turn rancid than olive oil, it is not therefore such a pleasant application; and not being possessed of any superior relaxing properties, the other will probably, for that reason, be commonly preferred.

"The disorder now under consideration, *viz.* a stiff joint, is so evidently one of those which particularly require the use of emollients, that almost every old woman has some particular form or other of recommending them; one of which I cannot avoid mentioning, as I have frequently known it used, and in two cases particularly, with very evident advantages,

262
Oil olive the best emollient.

263

viz. the web or omentum of a new-killed sheep, or of any other animal, to be applied over all the diseased parts directly on being cut out of the animal.

264
Omentum
of a new-
killed ani-
mal re-
commended

"In the two cases alluded to, one was in the knee, and the other in the hand; and the joints, from having been totally useless, were almost perfectly restored. The application should be renewed as frequently as possible, once a-day at least, or oftener when it can be done; for on being more than four or five hours applied it becomes disagreeable; and after that time, indeed, as it commonly turns stiff, it cannot then probably be of much service. The same kind of remedy, used in somewhat a different manner, I find recommended by Lieutaud, a celebrated French practitioner.

"I have been the more particular on this part of the subject, as I have often thought, with a little attention, the use of many joints might be recovered, which, from a mistaken notion concerning their causes, have generally from the first been considered as incurable.

265
Treatment
of a white
swelling
when mat-
ter is form-
ed in it.

"The disorder has hitherto been supposed not to be so far advanced as to have occasioned the formation of matter; for when come that length, no considerable advantages can be expected from any of the remedies as yet recommended: but even in that state of the complaint, if the patient's health does not absolutely require it, amputation of the member should by no means be immediately had recourse to, as it most frequently is. For by paying attention to open the different abscesses soon after their formation, the matter may in that way be pretty certainly prevented from destroying the capsular ligaments of the joints, which, if once effected, would no doubt in time render that operation necessary.

266
Of the pro-
per period
for ampu-
tating limbs
affected
with white
swellings.

"It may be here observed too, with respect to the most proper period of the disease for amputating such limbs, that, even in point of success from the operation, it ought never to be advised till the complaint is pretty far advanced: for though, *a priori*, it might be imagined, that the more early in the disease amputation of the member is had recourse to, the more successful it should prove; and although this, indeed, has been made a common argument for amputating very early in every case of white swelling, yet, however plausible the observation may appear, it will not, from experience, I am certain, be found to hold good. For in this disorder especially, I have constantly observed, that amputation has more frequently succeeded, that is, a greater proportion of such patients have recovered from it, who have previously been considerably reduced by diarrhoeas and other weakening symptoms, than of such as have still remained in a full plethoric habit of body.

"In the former, when the constitution has not been too much broken, and which practitioners have always in their power to guard against, the several symptoms of hectic which previously took place, are commonly removed in a very few days after the limb is taken off. No high inflammatory affections are ever produced; the patient daily mends in his health; and a complete cure, if the patient has not been too much reduced, is generally very soon obtained. In the latter, again, the very reverse of all these circumstances occur: the pa-

tient, from being in high health at the time of the operation, is generally thrown into a smart inflammatory fever; which is no doubt very often got the better of, but which frequently either carries off the patient immediately, or produces such effects as he never thoroughly recovers from.

"So that in no case whatever should amputation be had recourse to, until every probable means for saving the limb has been tried in vain.

"All the different observations hitherto made upon the treatment, relate particularly to the rheumatic species of the disorder; and when had recourse to in time, and duly persisted in, they will frequently be found of service: but when the disease is so far advanced as to have destroyed the capsular ligaments of the joint, and perhaps even the cartilages and bones themselves, amputation of the member is then no doubt the only resource.

"In the more fatal species of white swelling, *viz.* A scrophulous scrophulous, as I know no certain remedy for scrophulous, even in its milder form in the soft parts of the body, I cannot here pretend to offer any thing but by amputation, and even that not to be depend-

"In the small joints, when the diseased parts of the bone begin to cast off, a cure may in that way, by assisting the efforts of nature, be sometimes obtained; but in all the large joints, as the knee, ankle, &c. it is not probable that any other resource than amputation will ever afford much relief. And even the effects of that operation can seldom be depended on as lasting; for when the general scrophulous taint still subsists in the constitution, the disorder will most probably appear again in some other part; which, however, in the advanced stages of the disease, it is sometimes necessary to run the risk of, the pain being often so tormenting as to make it more eligible to submit to any hazard rather than to bear it longer.

268
When pal-
tation is determined against, as there being almost a certainty of the complaint soon returning, from the scrophulous disposition appearing very strong in the system, it then becomes necessary to have recourse to palliatives, so as to render the complaint as tolerable as possible; and with this view, opiates in large doses, by moderating the pain and procuring rest to the patient, will in general be found the principal remedy. In other respects, all such medicines and articles of regimen as are found beneficial in scrophulous, may be had recourse to."

269
Of encysted
tumours.
To the head of abscesses we may likewise refer those tumours which are contained in cysts, and which sometimes increase to an extraordinary size. These appear on the head, the eyebrows, or other parts of the body, and are at first but of a small size. They are seated in the adipose and cellular membrane; whence it not unfrequently happens that they take place in the viscera themselves, where they are almost always mortal. The contents of these tumours are very different in consistence. Sometimes they are filled with a substance of the consistence of honey, and are then thence called *muciferous* tumours; sometimes they are filled with an harder substance, and are then called *atheromatous* tumours; at other times they are filled with a substance of the consistence of fat, and are then called

Theory.

called *scatomatous*. Sometimes, however, they are found to be replenished with a fluid lymph coagulable by fire, and are then called *hydatids*.

Tumours of this kind are easily distinguished from all others, as having neither heat, pain, nor pulsation, as is to be observed in those which incline to suppurate. Sometimes, however, they will burst like abscesses, and the matter which is in them will flow out; but unless the whole cyst which contained it be removed, the ulcer refuses to heal, and even sometimes degenerates into a cancer.

271
Causes of
these tu-
mours.

Encysted tumours are often the consequence of an itch, *tinea capitis*, or other cutaneous disorder; and sometimes they arise after ulcers have been hastily dried up: but it also frequently happens that people are born with them, or that they arise spontaneously without any apparent cause.—When they are recent, and neither very large nor hard, they may sometimes be dissipated by the application of the common topical remedies made use of for resolving inflammations. But if these should not succeed, the only method is to dissect off the bag from the parts to which it adheres, preserving it as much as possible from being wounded; because then the operation becomes more difficult. If this cannot be done, they must be consumed by caustic; and where this operation is performed in time, there is seldom any danger, though Plater instances a young man who died in consequence of a very large tumour of this kind on the scapula, which had arisen after a *tinea capitis*.

272
Tumours
in the eye-
lids.

Tumours akin to these frequently are met with in the eye-lids. Sometimes they are of a soft consistence, and sometimes harder: but the cure is the same in both, namely excision; carefully observing to take off all the roots, either by caustic or the knife, lest the distemper should return.

273
Of gan-
glions in
the tendons.

Ganglions of the tendons may also be taken notice of here; which though they never come to suppuration, yet sometimes break, and discharge a fetid sanies. These arise in the tendons which are most employed in the common offices of life; and hence are frequently to be met with in the tendons of those muscles which move the fingers. Plater gives an instance of a ganglion which destroyed the patient. It was situated on the *tendo Achillis*; and took its rise from the person's jumping out of a carriage, at which time he felt an acute pain in that part. A tumour began to arise on the inside of the tendon; which being thus compressed, swelled out on each side of it. Being situated in such a place, surrounded with membranous parts, the wounding of which would have been very dangerous, surgeons of character declined the performing of any operation upon it; but the patient having applied to some empirics, the tumour, by means of their applications, increased to the size of the man's head, and at last began to discharge an ichor, at the same time that he was seized with an hectic. Amputation was now proposed: but as the patient refused to submit to the operation, an incredible quantity of putrid sanies discharged itself daily from the place; which increasing the fever, soon destroyed him. All this time the tumour, though grown hollow by the discharge, yet increased in its circumference at the bottom; so that the two opposite sides of it almost met on the fore-part of the leg.

In the cure of ganglions, we are never to attempt to bring them to suppuration: for of this they are incapable; and if unfortunately they should increase in size and burst, they will only discharge such an ill-conditioned sanies as that above-mentioned. The only method, therefore, is to attempt discussion. This is frequently accomplished by friction, and keeping a piece of lead on the part. Some commend plasters of different kinds; but as all of these are of a relaxing nature, there is great danger of their increasing the bulk of the tumour, at the same time that they render it softer. If, however, discussion shall be found impracticable, these tumours may be extirpated with the knife; but in such operations, great care is to be taken not to wound the tendon, lest the mischiefs already enumerated, arising from such wounds, should ensue.

The only other kind of tumours which can be referred to the head of abscesses, are those very malignant ones called *cancers*.—These most commonly arise in the glandular parts of the body, where they are occasioned by any bruise or contusion, sometimes a very slight one: and hence they are more common in the lips, and in the breasts of women, than in any other parts of the body.—Cancers have been generally distinguished into *occuli* and *open*. By the former are meant such hard scirrhus swellings as are attended with frequent shooting pains, and which at last generally terminate in the latter.

By the *open cancerous ulcer*, is understood that species of sore which commonly succeeds to hard swellings of the glands; although in some instances it occurs without any previous hardness. The edges of the ulcer are hard, ragged, and unequal, very painful, and reversed in different ways, being sometimes turned upwards and backwards, and on other occasions inwards. The whole surface of the sore is commonly very unequal, there being in some parts considerable risings, and in others deep excavations. The discharge, for the most part, is a thin dark-coloured fetid ichor; and is often possessed of such a degree of acrimony as to excoriate, and even destroy, the neighbouring parts. In the more advanced stages of the disease, too, by the erosion of blood-vessels which occurs, considerable quantities of pure blood are sometimes discharged.

Patients labouring under real cancerous affections, universally complain of what they term a *burning* heat over the whole ulcerated surface; which in general, it may be remarked, is the most tormenting symptom that attends the disorder; and those shooting lancinating pains, which were troublesome in the more occult state of the complaint, become now a great deal more so.

These are the most frequent symptoms which attend an ulcerated cancer; but the appearances of such sores are so various, that it is almost impossible in any description to comprehend every one. When two, three, or more, however, of those enumerated, concur together in the same ulcer, we may always be pretty certain of its being of the cancerous kind.

Concerning the causes of cancers, there have been a great many conjectures, but without any solid foundation. It is of some moment, however, to determine whether they arise from some general disorder in the system,

Theory.

system, or whether they are only to be accounted local diseases. Many of the most eminent practitioners have been of opinion that they arise from a general disorder of the system; and hence consider them as totally incurable even by extirpation, as the latent seeds of the disease, in their opinion, will not fail to bring on a return of it somewhere or other. Of this opinion the late Dr Monro appears to have been; and in a paper on this subject in the Edinburgh Medical Essays, declares, that "of near 60 cancers which he had been present at the extirpation of, only four patients remained free of the disease at the end of two years." From this bad success, and the violent progress of the disease, he finally concludes against the extirpation of cancers, and proposes only the palliative method of cure. But later practitioners have been a great deal more successful; and a late publication by Mr Hill surgeon at Dumfries has put the usefulness of extirpation beyond a doubt, when the operation is performed in time: though, after the disease has continued long, and the virus been absorbed, the whole system acquires a cancerous disposition, and the disease almost certainly recurs in some other part. From internal medicines we can expect little or nothing in the cure of cancers; and external applications can do no more than palliate. Great expectations were formed from the powder and extract of cicuta; but it has so universally failed, that few put much confidence in it at present. However, it has sometimes been of service in cases of a simple indurated gland; and even where the disease has been farther advanced, it has produced a better discharge, and diminished the fetor of the sore; but as it cannot be depended upon for a radical cure, a delay of the operation is never to be recommended.

SECT. V. Of Hernia.

287
Definition
of an her-
nia.

THE name of *Hernia* might with propriety be applied to every swelling occasioned by the dislodgment of parts from those boundaries within which, in a state of health, they are contained; but the general acceptance of the term implies a tumour produced by the protrusion of some part or parts from the cavity of the abdomen.

282
Situation
and con-
tents of
hernia.

The parts in which these swellings usually appear, are the groin, scrotum, labia pudendi, the upper and fore part of the thigh, the umbilicus, and in different points between the interstices of the abdominal muscles.

If the situation of such tumours be various, the viscera which produce them are still more so; instances having occurred of the stomach, uterus, liver, spleen, and bladder, being found to form their contents. But a part of the intestinal canal, or a portion of the omentum, are from experience known to be the most frequent cause of their formation.

283
Their dif-
ferent ap-
pellations.

From these circumstances of situation and contents, all the different appellations are derived by which hernia are distinguished. Thus they are termed *inguinal*, *scrotal*, *femoral*, *umbilical*, and *ventral*; from their appearing in the groin, scrotum, thigh, navel, or belly. When the tumour is confined to the groin, the hernia is said to be incomplete, and is termed *bubonocoele*; but when the swelling reaches down to the bottom of the scrotum, the rupture is then supposed

to be complete, and the disease obtains the name of *scrotal rupture*, or *oshibocoele*.

When a portion of gut alone forms the tumour, it is called an *enterocoele*, or *intestinal hernia*; when a piece of omentum only has got down, it is termed *epiplocele*, or *omenta hernia*; and if both intestine and omentum are down, it is called an *entero-epiplocele*, or *compound rupture*.

A portion of some of the abdominal viscera getting into the tunica vaginalis testis, forms that species of hernia to which new-born infants are liable, termed by Haller the *hernia congenita*. The testicle and protruded intestine being here in contact with one another, the tunica vaginalis testis forms the hernial sac.

If the gut, or other parts which have fallen down, be again pushed into the abdomen, and are retained there by proper bandages, or any other means, in that case the passage is soon closed up, and no return of the disorder is observed. But this being neglected, and the gut being allowed to remain long down, the parts forming the passage seem thereby in a great measure to lose that power of adhesion which naturally they are known to possess: instances of such cases having occurred where no art has been able to produce this wished-for obliteration of the opening.

The hernia congenita is usually produced in the manner now described: it is probable, however, that the same disorder may, and frequently does, occur from this passage between the abdomen and testicle, after having been once closed, being again rendered pervious, in consequence of the parts being over-stretched by those violent fits of coughing, crying, and other convulsive affections to which children soon after birth are now and then liable. The intestinal canal and other viscera being on such occasions pushed with violence against all the containing parts, these will most easily give way where the least degree of firmness occurs; and this we may readily suppose will most probably happen in such parts as have been most recently united. In this manner, it is probable that the greatest proportion of those cases of hernia are produced which occur in the early months of infancy; and it is probable, that in some occasions, in more advanced periods of life, the same species of hernia may likewise occur from the same cause.

The causes which tend to the production of hernia in its more usual form, are as follows:

I. The containing parts of the abdomen we know to be elastic and compressible; whatever, therefore, tends to produce a diminution of capacity in the cavity of the abdomen, must occasion a proportional degree of risk of some of the contained parts being pushed from their natural situations. Violent coughing, crying, laughter, or great bodily exertion, are attended with more or less contraction of the abdominal muscles, and particularly of the diaphragm; and as the contraction of these muscles must always diminish the abdominal cavity, these causes therefore are frequently found to be productive of hernia.

II. Falls, in consequence of the derangement they produce in the abdominal viscera, from the sudden and violent shock with which they are often attended, are not unfrequently the immediate causes of hernia.

III. Persons of a preternatural laxity of frame are very liable to hernia. The containing parts of the abdo-

men

Theory. men, from the want of a sufficient tone and firmness, are unable in such people to resist on all occasions the weight of the different viscera; and they are therefore more particularly exposed to disorders of this kind on the slightest application of any of the causes already mentioned.

IV. Sprains are apt to induce a laxity of the part injured; and have therefore a similar influence in inducing hernia with general laxity.

V. It has been observed, that the people of those countries where oil is much used as an article of diet, are particularly liable to hernia.

In whatever parts the parietes of the abdomen happen to be weakest, these various causes will most readily operate in producing hernia; and accordingly we find, that descents of the bowels usually occur only in such parts.

The parts which from anatomy we would *a priori* suspect to be most liable to such protrusions, are the openings in the external oblique muscles; the arch formed by Poupart's ligament for the passage of the great blood-vessels of the thigh; and the umbilicus, where the same degree of firmness does not take place as is met with in the rest of the tendinous expansion of the abdominal muscles. Sometimes, however, it happens, that parts of the viscera are protruded between the interstices of the different muscles of the abdomen; but these are not frequent occurrences.

In whichever of these situations a protrusion of any portion of the intestines occurs, except in the case of the hernia congenita, as all the viscera are contained within the peritonæum, a portion of that membrane, it is evident, must be carried down together with the parts protruded; and in every such instance, it is this portion of the peritonæum, which goes down along with the gut, that is termed the *hernial sac*. The size of this sac is various in different subjects, and in different stages of the same disorder.

On the first appearance of the disease, the sac is commonly of no very considerable size, as such swellings seldom acquire any great bulk at once; but by repeated descents of the bowels, the sac comes to be pushed lower and lower, till in some instances its bulk becomes very considerable indeed; and when in this advanced period of the disorder the sac happens to be laid open, it is found to contain either large quantities of omentum or intestine, and frequently large portions of each.

As the peritonæum has this property in common with many other parts of the body, of thickening according to the degree of any gradual extension applied to it, so in many instances the thickness and firmness of the hernial sac are often really astonishing.

Although every instance of a bowel protruded from its natural situation is to be considered as a derangement, and as such ought to excite our attention for its reduction; yet daily instances occur both of recent hernia, and of those of longer standing, in which no bad symptoms are produced from such protrusions of the viscera. Thus it is well known, that hernial swellings of every kind very frequently happen, without the patient suffering in any other manner than from the inconvenience arising from the bulk of the tumours. But in general the case is otherwise; troublesome symptoms most frequently occur; and at all events,

when the reduction of a hernia can be accomplished with any kind of propriety, it ought always to be effected as quick as possible.

All the bad symptoms which are found to occur in hernia, proceed, as may be readily supposed, either from obstruction to the passage of the feces when the intestinal canal forms the tumour, or from a stoppage of circulation occasioned by stricture on the prolapsed parts; so that the attending symptoms, it is evident, will be always more or less hazardous, according to the nature of the parts so protruded.

Thus, when omentum alone forms the substance of hernial swellings, as that organ does not appear to be so immediately necessary for life as many of the other viscera, such tumours accordingly are not so frequently productive of bad consequences, at least they are seldom in any degree so hazardous as when a part of the alimentary canal is either protruded by itself or along with omentum.

Although this, however, is in general the case; yet it does sometimes happen, that even an omental rupture is productive of no small degree of danger. When a stricture so complete upon it occurs as to occasion a stoppage of circulation in the protruded part, mortification with all its bad consequences must be the certain event: And besides, the connection between the omentum, stomach, and other viscera, is such, that a sudden descent of any considerable portion of the former sometimes brings on vomiting, hickup, and other troublesome symptoms: And lastly, although a rupture containing omentum only, might not of itself produce any thing bad; yet as the passage through which the omentum has slipped, must of necessity continue open so long as that viscus remains protruded, and as that circumstance alone must so long as it continues render it more easy for a portion of gut likewise to get down, this of itself is a sufficient reason for even this species of hernia deserving the serious attention of practitioners.

But whatever the contents of such swellings may be, as their remaining in some instances for a considerable length of time without being productive of any bad symptoms, must proceed entirely from the circulation continuing to go freely on, notwithstanding the derangement of parts; so, whenever a stricture occurs upon the protruded viscera, sufficient to produce either a stoppage of the circulation, or of the fecal contents of the alimentary canal when a portion of gut forms the disease, the following in general are the symptoms which accrue.

An elastic colourless swelling is observed at the part affected. A slight pain is felt not only in the swelling itself, but, if part of the alimentary canal is down, an universal uneasiness is perceived over the whole abdomen; and this pain is always rendered worse by coughing, sneezing, or any violent exertion. The patient complains of nausea; frequent retching; can get no discharge by stool; becomes hot and restless; and the pulse is commonly found quick and hard. When the swelling is entirely formed by a portion of gut, if no feces be contained in it, it has a smooth, equal surface; and is easily compressible, but instantly returns to its former size on the pressure being removed: but, in gut-ruptures of long standing, where hard feces have collected in the protruded bowels, considerable

able inequalities are detected. When again the tumour is composed both of gut and omentum, its appearance is always unequal, it feels soft and somewhat like dough, and of course is not so elastic as when part of the intestinal tube only is down; for although, like the other, it is compressible, it does not so readily regain its former dimensions on the pressure being taken off.

It has been a received opinion, that in cases of strangulated hernia the symptoms should be less violent when the intestine is accompanied by a portion of omentum, than when gut alone is down. Little or no difference, however, is produced by this circumstance; for when a gut becomes obstructed and inflamed, the symptoms thereby induced are nearly the same whether the omentum be down with it or not.

293
These symptoms cannot be occasioned by the mere descent of the omentum.

It will be readily supposed, however, that the symptoms we have described never can happen from the presence of omentum *only*: For although stricture produced on a portion of omentum, even when no part of the intestinal tube is down, does now and then occasion a good deal of distress, such as pain in the part, sickness, vomiting, and twitching pains through the whole belly; yet no obstruction of the gut ever occurs from this, and of course none of the symptoms ever prove so alarming as when any part of the gut is affected. If these symptoms we have described as being produced by a strangulated gut, are not now obviated by a removal of the stricture which produced them, the nausea and retching terminate in frequent vomitings, first of a bilious, and afterwards of a more fetid matter; the belly becomes tense; the pain turns more violent; a distressing convulsive hiccup comes on; the fever, which before was not apparently of much consequence, now becomes very formidable; and a total want of rest, with a very disagreeable state of anxiety, continues through the whole course of the complaint.—These symptoms having gone on with violence for some time, the patient is at last commonly suddenly relieved from all manner of pain; when he flatters himself every risk is for certain over. But instead of that, the pulse, from having been hard and frequent, becomes languid and interrupted; cold sweats break out over the whole body, but especially on the extremities; the eyes acquire a kind of languor; the tenderness of the abdomen subsides, and the swelling of the part affected disappears; the teguments covering the parts, which before were either of a natural appearance, or had somewhat of a reddish inflamed cast, now acquire a livid hue, and a windy crepitous feel is distinguishable all over the course of the swelling. If the protruded parts have not of themselves gone entirely up, their return is now in general easily effected by a small degree of pressure, and the patient then discharges freely by stool; but the cold sweats increasing, the hiccup turns more violent, and death itself is at last ushered in by its usual forerunners, subsultus tendinum, and other convulsive twitchings.

These are the ordinary symptoms of what is termed a *strangulated or incarcerated gut-hernia*: that is, when the parts protruded become so affected by stricture as to produce pain; and do not either return to their natural situations on the patient's getting into a hori-

zontal posture, or cannot even be immediately replaced by the hands of a practitioner.

In whatever situation a strangulated hernia occurs, the only rational method of cure, it is evident, must consist in the removal of that stricture which prevents the return of the protruded parts. It is that stricture which ought to be considered as the cause of all the mischief; and unless it be removed, nothing effectual can be done for the relief of the patient.

Various methods have been attempted by practitioners for the removal of stricture in these disorders; all of them, however, may be comprehended under two general heads.

I. Such as effect a reduction of the protruded parts, without the interposition of incision or any surgical operation properly so called; and,

II. A division of the parts producing the stricture, so as to admit of a replacement of the deranged viscera, constituting what is termed the *operation for the hernia*.

The remedies to be employed for accomplishing the first of these, are, a proper posture of the patient, with the manual assistance of a practitioner; blood-letting, stimulating glysters, opiates, the warm bath, and proper applications to the tumour itself.—If these fail, there is then no other means of cure left but the operation of dividing the integuments, and replacing the viscera in the manner afterwards to be described.

SECT. VI. Of an Erysipelas, Gangrene, and Mortification.

It has been already observed, that inflammation of a membrane produces an erysipelas, as the inflammation of a muscular or fleshy part produces a tumour and abscess. The disease is attended with a much greater fever than a common inflammation, and it is much more dangerous. The internal medicines proper in these cases have been taken notice of under the article MEDICINE, n° 324. It remains therefore to treat only of the external applications; and here we find, that till very lately there have been such strong prejudices against applying any thing cooling or emollient to parts afflicted with an erysipelas, that the most absurd practices have been adopted. Those who maintain the chimerical opinion that a volatile acid was the cause of the disease, advise chalk to be strewed upon the inflamed part: some use fomentations of soap; others medicated bags filled with elder-flowers, moistened with wine and water or vinegar: some a decoction of sheep's dung in wine; while others employed epithems composed of Venice treacle and spirit of wine. Some thought lixivium and oil a better remedy, while others preferred a poultice made of oatmeal and water made without boiling.—Hoffman adhered to the method of applying dry medicated powders; and modern physicians have followed him, though they have thought proper to substitute wheat-flour, or Peruvian bark in powder, as preferable to the remedies recommended by him. Amidst all this variety of prescriptions, however, the use of cooling and emollient applications has been almost universally reprobated, from a notion of their checking perspiration and repelling the disease: but Dr Kirk-land, who has treated this matter at great length, is entirely of opinion that emollients are the only re-

295
Method of cure.

medies to be depended upon; and recommends a cataplasm composed of four ounces of the soft crumb of bread, a quart of milk, and four ounces of hog's lard, boiled slowly together till the poultice acquire such a consistence that it will not stick to the fingers. Poultices, he says, can never be good without long boiling; but as they are at any rate inconvenient when the disease is seated in the head and face, he recommends cooling emollient ointments.

It is not very uncommon for an inflammation, whether of the common or erysipelatous kind, to terminate in a gangrene and mortification: nor is it uncommon for this disease to arise in different parts of the body from internal causes, without any external tumour appearing; or at least the tendency to gangrene is so strong, that it may be said to take place almost instantaneously. The internal causes of gangrene, according to Mr O'Halloran, are,

O'Halloran

I. An highly vitiated disposition both of solids and fluids; and of this our author reckons four classes. 1. When the solids and fluids are so much vitiated, that all attempts to restrain the disease are vain, and only hurry on death the sooner. 2. When the whole body is vitiated, yet in a less degree than the former; in which case, by strong stimulants and cordials, the patient may survive by means of nature throwing the general vice to some particular part, by the loss of which life is preserved. 3. Where the malignity is much less, so that the patient may be cured without the loss of a limb. And, 4. Where the blood, though not highly vitiated, is yet deprived of its balsamic properties, so that all forces are healed with great difficulty and very considerable length of time.

II. Gangrene may arise from an hot, bilious, and inflammatory state of the blood; in which case the parts are endowed with a great degree of sensibility, and a slight hurt will frequently bring on the most alarming symptoms.

III. Where there is a grossness of the humours, with no great degree of activity in the blood itself, and a wound or hurt supervenes. Here the system has not sufficient power to raise the degree of inflammation necessary for producing pus; nor often, by the assistance of art, to discuss the tumour.

IV. A concentered disposition of the juices often brings on the most dreadful species of gangrene. In this, from the hurting of a wart, a slight itching, &c. a sharp humour will gradually form, by which the muscles, ligaments, blood-vessels, and bones, are gradually consumed; nor will it cease its advances till the injured parts are totally separated from the body.

V. Another species of gangrene, Mr O'Halloran says, is endemic to the poor of Ireland; and consists in an anchylosis and caries of the bones of the tarsus, coming with or without hurt. The cause of this he supposes to proceed either from the extreme poverty of these people, or from their working continually in bogs and marshy lands.

300
Signs of an
approach-
ing gan-
grene.

A gangrene is known to be approaching, when the pain, redness, and tension of the inflamed part, together with the concomitant fever, increase, at the same time that little change is made in the size of the tumour. Mortification or sphacelus first appears by a change of colour in the part, from a bright red to a leaden or livid cast, with small vesicles containing a thin acrid

serum dispersed over its surface. In the mean time the pain abates; the pulse sinks, but continues frequent; the tumour at last loses its tenderness, and turns quite black and flaccid. This blackness is the sign of the mortification becoming complete; the part, meanwhile, losing all sensation, at the same time that it emits a considerable fetor; at last, too, a softness or flaccidity in general takes place, together with an entire dissolution of the different parts of which the organ is composed. There are, however, some instances of what is called *dry gangrene*, in which the parts continue totally mortified for a great length of time, without either turning very flaccid, or running into dissolution. But such cases never occur from inflammation; they happen commonly from the flow of blood to such parts being put a stop to by compression of one kind or another, as tumours, ligatures, or other similar causes, obstructing the principal arteries that used to supply them; which, when the stoppage of the circulation is complete, always occasion a very slow, tedious, mortification; and as the parts in such instances are no longer supplied with fresh quantities of fluids, while a considerable evaporation must still be going on, such a degree of humidity cannot, therefore, possibly occur as does in other cases of gangrene. So that species of the disorder has, perhaps, with propriety enough, been termed the *dry gangrene*.

301
Of a dry
gangrene.

There are many other varieties of the disease enumerated by authors, as the *white gangrene*; in which the parts supposed mortified do not turn black, but retain nearly their former colour, &c. Whether such complaints, however, can with propriety be denominated *gangrene* or not, may properly be doubted: but as it is chiefly that species of the disorder which succeeds to inflammation that is now particularly to be treated of, and in which no such varieties are ever observed, it is not here necessary to carry the inquiry farther; and that especially as nearly the whole mode of treatment, afterwards to be pointed out, applies with almost equal propriety to every variety of the disease.

302
Of the
white gan-
grene.

Of all the inflammatory complaints to which the *Erysipelas* system is liable, that species of the disorder termed *Erysipelas* is observed most frequently to terminate in gangrene; and whenever phlegmon is in any degree conjoined with an erysipelatous affection, which it not unfrequently is, it seems thereby to have acquired the same tendency, by being, as was already remarked, more difficult to bring to suppuration than the true phlegmon, and by going on more frequently to the mortified state.

303
Of the
Erysipelas
most liable
to end in
gangrene.

The best and most effectual means of preventing mortification in every case of inflammation, is to endeavour either to obtain its resolution or suppuration; the different remedies for both which purposes have already been fully pointed out. But in some cases, the disorder is far advanced, and gangrene already begun, before the surgeon's assistance is called in: in others, the inflammation runs so high, and proceeds so quickly, that gangrene occurs notwithstanding the use of all the remedies that can be applied; in some instances, as we have already observed, so quickly, even that the inflammatory state is scarcely thoroughly discerned till mortification appears to be beginning.

304
Means of
preventing
the disease.

This is most remarkably the case in carbuncles, which

305
Of car-
buncles.

what

Theory. what by the French are termed *charbons*; in which the inflammation proceeds so rapidly to mortification, that there is seldom any evident tumour raised, the parts turning black, and ending in real gangrene, often in the course of 24 hours from the first attack.

The quick progress usually made by this disorder renders it the worst, and perhaps the most dangerous, species of inflammation. For when it occurs internally upon any of the viscera, as it sometimes does, it must, probably in every instance, prove fatal, as no remedies we are acquainted with can ever prevent its progress towards the last stage of mortification. Externally, indeed, when not very extensive, and not seated on any of the large blood-vessels and nerves, carbuncles are frequently got the better of; that is, with the loss of the affected parts.

306
They al-
most always
occur from
a putrid
state of the
juices.

As carbuncles always appear without any evident external cause, they are in general most probably owing to a scorbutic or putrid state of the fluids; for when putrefaction prevails in the system, every inflammatory affection that occurs, proceeds much more readily to the mortified state than inflammation in other circumstances ever does. This opinion with respect to the cause of carbuncles depending upon a putrescent state of the system, is particularly confirmed by their occurring most frequently as a symptom in pectilential disorders; for although they are sometimes met with even in this country, where the plague is now never known, yet the real carbuncle is far from being a common occurrence.

The internal remedies proper for preventing gangrene have been already mentioned under the article MEDICINE, n° 281. In the way of external application, a variety of remedies have been pointed out, and particularly those of the antiseptic kind; such as all the warm gums and balsams, ardent spirits, and even alcohol: and to admit of their nearer application to the sound parts, with a view to the preservation of these from putrefaction, deep scarifications through the diseased and into the sound parts have been generally recommended. But although such articles may be of use in preserving dead animal-substances from corruption; yet that they will always prove serviceable in the same manner in living bodies, is probably very much to be doubted. And it is even apprehended, by the strong irritation they always occasion when applied to a living fibre, that, in such cases as the present, they may rather do mischief; it being only a very slight degree of inflammation that is required to bring on a suppuration. The incisions, too, when carried into the sound parts, with a view to facilitate the operation of such remedies, may likewise do harm; not only from the risk of wounding the blood-vessels, nerves, and tendons, that lie in the way, but also by allowing a free and farther entrance of the putrescent fluids into the parts not yet affected: and unless they are carried so deep as freely to reach the sound parts, applications of the antiseptic kind can never have any effect in answering the purpose for which they were intended.

309
Scarifica-
tions of no
advantage.

For these reasons, and from never having observed any advantage to accrue from scarifications in mortification, the best practitioners are of opinion that they may be entirely laid aside. Theriac was in former times, and still is with some practitioners, a very

common application in every case of gangrene; but, from the best experience, it seems never to produce any evident good effects.

All the advantages commonly observed from the great variety of applications recommended for gangrene, are obtained with more ease, and generally too with more certainty, from the use of any gentle stimulating embrocation; which, by exciting a slight irritation upon the surface, and especially when assisted by a free use of the bark, at last commonly produces such a degree of inflammation as is wished for. With this view, a weak solution of sal ammoniac in vinegar and water has been known to answer exceedingly well; a dram of the salt to two ounces of vinegar and six of water, forms a mixture of a very proper strength for every purpose of this kind; but the degree of stimulus can be easily either increased or diminished, according to circumstances, by using a larger or smaller proportion of the salt.

Although, for the reasons formerly advanced, incisions may not in general be proper; yet in such cases where the mortification runs very deep, it is sometimes of service to make scarifications into the diseased parts, so as to remove part of them; which by taking off a considerable load perhaps of putrid dead flesh, not only lessens the fetor, which in such cases is always considerable, but often renders it more easy for the sound parts to free themselves from the remainder. When with this view, however, incisions are had recourse to, care should always be taken that they be not carried the length of the sound parts.

Whenever, either by the means recommended, or by the effects of a natural exertion of the system, a slight inflammation appears between the diseased and sound parts, we may in general, with tolerable certainty, expect, that in due time a thorough separation will take place; and when a full suppuration is once fairly established, there can then be little doubt but that the mortified parts will be very soon and easily removed.

A separation being altogether effected, the remaining part being then to be considered merely as a simple purulent ulcer, may be treated in the same manner as such sores generally are, with very slight easy dressings; at the same time that proper attention must always be paid to the support of the general system, by the continuance of a nourishing diet, the bark, and such quantities of wine as may seem necessary.

Although, however, such ulcers as remain after gangrenous affections that have not been very extensive, may in general be healed in the manner now mentioned; yet in mortifications seated on the extremities, and that have penetrated to the bones, it sometimes happens that the whole surrounding soft parts come to be destroyed, so that amputation of the member is thereby rendered necessary. Amputation, however, should never be had recourse to, till a full and thorough separation of the mortified parts has taken place: for it is now, in every case of gangrene, from undoubted experience, an established maxim in surgery, That though the parts immediately contiguous to those evidently diseased may outwardly appear sound; yet as there can be no certainty of those even directly below remaining so, till a full stop, or even till a complete separation, of the mortification has been

^{Theory.} been produced; so, till that has evidently taken place, it is in such cases a general rule never to amputate a member; there being no other security for the disorder not returning, and that immediately too upon the remaining stump.

It must be observed, however, that so soon as an entire separation of the gangrene has occurred, no time should be unnecessarily lost in having recourse to the operation; for so long as any of the corrupted parts remain in contact with the sound, the system must still be suffering considerably by the constant absorption of putrescent particles, that so long will undoubtedly take place.

SECT. VII. Of Diseases of the Bones.

³¹³
^{Exostosis} THE bones, as well as the softer parts, are liable to be swelled, either throughout their whole length, or to have tumours formed on particular parts of them.

Exostosis is one species of tumour of the bone; but, according to Mr Bromesfield, in strictness of definition, no swelling should be called so, but an excrescence continued from a bone, like a branch from the trunk of a tree. Under this head, therefore, is ranked the *næde*; which may be produced by external injury, such as contusions and fractures: but in both these cases, the tumour has had the epithet of *benign* affixed, and can hardly be called a disease, as pain is seldom consequent to such risings from the bone; but it rather should be termed a deformity.

There are risings or tumours observable on the bones which are often the consequents of venereal virus, and are termed *tophi*, *gummi*, or *nædes*.—Tophus, is a soft tumour in the bone; and seems to be formed of a chalky substance, that is intermediate between the osseous fibres. These cretaceous extravasations sometimes are found on the ligaments and tendons, as well as on the bone; and when collected into a toph, may sometimes be taken out by the knife. We have many instances, where chalk stones in gouty people make their way out through the skin of the fingers and toes.

³¹⁴
^{Tophus.} ³¹⁵
^{Gummi.} Gummi is likewise a soft tumour; but is on the surface of the bone, between it and the periosteum; and its contents resemble gum softened, from whence it has taken its name. Possibly, by obstruction in the nutrient vessels of the bone, a rupture of some of them occasions the ferous liquor to escape, which, by making its way between the fibres of the bone, arrives at its surface; and being detained by the resistance of the periosteum, its most liquid parts being evaporated, and the remainder condensed by the inflammation, and consequently this inelastic covering being stretched, it becomes inspissated, and forms this species of *exostosis*, as it is generally called. When this is the cause, and the indispotion of the habit in general got the better of, pressure by a steel instrument, adapted to the part affected, is the proper cure.

³¹⁶
^{Nædes.} The confirmed venereal node has the appearance of a divarication of the osseous fibres, probably from some inspissated humour obstructing the nutrient vessels, but not extravasated; this occasioning an extension of the periosteum, produces a violent pain, which, when nocturnal, is the characteristic of a venereal cause. When only the periosteum is thickened, but the bone not affected, a course of mercury, by attenuating the obstructed humour, and fitting it to be carried out of the

body by the proper outlets, will often produce a perfect cure: but when the bone itself is diseased, this method will fail. But here the division of the extended periosteum has been known to give perfect ease.

The usual method, formerly, was to apply a caustic equal to the extent of the node, which being laid bare, required exfoliation before it could be cicatrized. If the incision is made early, that is, before matter be formed under the invelling membrane, it seldom requires exfoliation; and, as we often find that the bone itself is not affected, but only the periosteum thickened, we may be deceived even after a careful examination: it is therefore proper that the patient should be pretty far advanced in a course of mercurial unction, before even the incision is made; for, should the tumour decrease and the pain abate during the course, chirurgic assistance, with the knife, most likely may become unnecessary.

The name *exostosis* may not be improper to those ³¹⁷
^{Of a spine} excrescences that are found on the surface of a bone in a *spina ventosa*, or in consequence of a caries from other causes; and it is not unfrequent for the ossific matter, being let loose by the separation of a caries, to flow in such quantity as even to incrust, and sometimes to form a case to a diseased bone. But where a bone is enlarged throughout its whole length, or its epiphyses become swelled, as in scrophulous cases, particularly in children, which case is in them called *pararthrocæce*, such swellings cannot with propriety be ranked in this class; and whether scorbutic, scrophulous, or venereal leaven gives rise to these tumours of the bone, the habit of the body in general must be corrected, to give any chance of a cure.

A bone may become carious first in its internal parts; and that from external injury, as well as from a vitiated state of the animal-fluids. Authors seem not to agree as to the technical term for this kind of disease of the bones; some calling it *cancer* or *gangræna ossis*; others, *spina ventosa*, from the pointed exuberances usually attendant on this disorder of the bone; and some again, *teredo*, from the appearance of the carious bone, like wood that is worm-eaten.

It is universally allowed, that this disease takes its rise from matter being formed either in the diploë, or in the marrow: whenever obstruction is begun in the vessels expanded on, or terminating in, the medullary cysts, the consequence will be inflammation, and, if not early removed, will form matter; for this reason, this case may be called *abscessus in medulla*. ³¹⁸
^{Symptoms} Whenever, then, a patient complains of dull, heavy pain, of this deeply situated in the bone, possibly consequent to a temper- violent blow received on the part some time before, and though at the time the patient complains of this uneasiness, within the bone, the integuments shall appear perfectly sound, and the bone itself not in the least injured, we have great reason to suspect an abscessus in the medulla. Children of a bad habit of body, though they have not suffered any external injury, will often become lame, and complain of the limb being remarkably heavy; and though not attended with acute pain, yet the dull throbbing uneasiness is constant. If rigors happen during the time the patient labours under this indispotion, it generally implies that matter will be formed within the substance of the bone. On the age of the patient, and the

Theory.

Theory.

solidity of the bone, will in a great measure depend the next alarming symptoms, to those who are not acquainted thoroughly with the case and the constitution of the patient. As mothers and nurses are often inattentive to children on the first complaining of pain and heaviness in a limb, if, after rubbing it with their hand a few minutes, the child, amused by some new toy or play-fellow, think himself easier, the good women, as they cannot see any thing wrong, determine it a growing-pain, as they call it; but, soon after, the extremities of the bone formerly complained of begin to swell, or, possibly throughout its whole extent, it becomes enlarged; a surgeon is then sent for, who, if a man of experience, will know this to be an abscessus in medulla, or true spina ventosa, as it is called: if neither of these symptoms should be consequent to the first complaint, the great insensibility of the bone in some subjects will prevent that acuteness of pain usual in other parts where matter is formed, though the acrid matter is eroding the bone during the whole time it is contained within it. This matter at length having made its way through, arrives at the periosteum, where it creates most violent pain, as well from its sharpness as from its increased quantity, occasioning an extension of the periosteum. The integuments then become swelled and inflamed, and have a sort of emphysematous feel. On being examined by pressure, the tumour will sometimes be lessened, from part of the matter retiring into the bone: from this appearance to the touch, most likely the name of *ventosa* was added to the term *spina*. When we are assured of matter being under the periosteum, we cannot be too early in letting it out, as it will have a considerable deal of pain to the patient, though probable it may not be of any considerable advantage in respect to the carious bone; for, where the fluids in general are vitiated, no chance of cure can be expected from topical remedies; but where the constitution is mended, nature will sometimes astonish us in her part; as the carious bone will be thrown off from the epiphyses, or the teredines will be filled up by the ossific matter that flows from the parts of the bone where some of the spinæ have come away.

319
Of the method of cure.

If proper medicines are given, the children well supported, and the parts kept clean and dry, patience and perseverance will frequently give great credit to the surgeon. In case it should have been thought advisable to apply the hand of a trephine at the upper and lower extremities of the tibia, to give free discharge to the matter, the washing it away, as well as the small crumbings of the carious bone, by means of detensive and drying injections, has been known to contribute greatly to the curing this kind of caries, after the habit of body in general had been mended.

320
Of the friableness and shortness of the bones.

Besides those above-mentioned, the bones are liable to two opposite diseases; the one termed *friabilitas*, the other *mollities*: the former peculiar to adults, the latter more frequent in infants, though sometimes seen in adults, from a vitiated state of their juices.

The bones, when deprived of their cementing liquor, by passing through fire, become friable. From repeated salivations, and in old people, they have been rendered extremely brittle; inasmuch that in many subjects they have been fractured merely from their weight and the action of the muscles: but in such cases, this is not owing to the friability of the bones,

but to the loss of substance, from the erosion of the bone by an acrimonious humour thrown on it; to which cause perhaps may be attributed the disease called *rickets* in children. The effects of scorbutic humour in rendering the bones soft in many instances, have often been remarked.

From the observations we daily make, that the bones of rickety children become soft and flexible, in different parts of the same bones, though their shape is preserved; that the known effect on bones when soaked in an acid menstruum, is, that the cretaceous particles being destroyed, they become membranous; from these remarks, we are induced to attribute the species of the disorder to an acrimonious humour thrown on the bones, and obstructed in their internal vessels. By proper diet, gentle friction with coarse cloths, exercise, and cold bathing, these invalids will frequently get their constitution so much changed, as that by the time they arrive at the age of twenty years there shall not remain the least vestige of their former disease. The epiphyses are generally most affected in this species of the disorder.

For want of early attention to invalids of this sort, we find that their bones not only become soft, and yield to the powers of the muscles, but remain distorted the rest of their lives, though they have acquired a perfect degree of solidity. In such cases, correcting the vitiated juices only will not restore the bones to their natural state; therefore the assistance of a skilful mechanic is necessary both to support the parts improperly acted on, and to alter the line of direction of the distorted osseous fibres.

Though the curvature of the extremities, or thick-
322
ness of the ends of the bones near their articulations, may give the first alarm to those who are constantly with children, yet there are other symptoms that give earlier notice than these, which, had they been timely discovered by proper judges, it is highly probable that the curvature of the limbs in many children might not have happened. The belly generally becomes larger in this disease, from the increased size of the contained bowels, as it is not unlikely but that the mesenteric glands are the first parts obstructed; obstructions of the liver, spleen, and pancreas soon follow; the head then becomes enlarged; then a difficulty of breathing, which is generally supposed to be the effects of taking cold, succeeds; the sternum is elevated and sharp, and the thorax becomes contracted; the spine is protruded in several parts; the pelvis altered, according to the pressure of the parts within, and habitual inclination of the patient, at times, to obtain that line of direction in which the perpendicular from the centre of gravity may fall within the common base of the body, the extremities of the cylindrical bones, and the ends of the ribs, next the sternum, become enlarged; soon after this the bones in general become soft and flexible, yielding in such directions as the strongest muscles determine by their actions.

The bones of children who die of this disorder, we
323
observe, are not only rendered soft, but the vessels an-
ce of them within their substance are replete with blood, whose texture is totally broken, and has more the appearance of thin chocolate than blood: the periosteum in many places is separated, and the intermediate space between
the

323
Appearance of the bones after death.

Theory. it and the bone filled with extravasated fluid; and caries is almost as frequent as the separation of the periosteum. The muscles in such bodies generally appear pale and flabby.

325
Mr. Bromfield's method of cure.

Where the affection of the mesenteric glands is evident, Mr Bromfield asserts, that after a dose or two of the pulvis basilicus to empty the intestines thoroughly, the purified crude quicksilver is by much the most efficacious medicine to remove obstructions in those glands. When the belly begins to soften and subside, the chyle passes without interruption, and the child begins to get flesh; then the cold bath becomes truly serviceable, and the decoction or cold infusion of the Peruvian bark is a proper restorative; but the cold bath used too early, or the bark given before there is a free circulation of chyle through the lacteals, would be very injurious.

The mollities ossium, in some cases, may be produced from a redundancy of the oleaginous parts of the blood, or from a laxity of the solids, by which the fluids are not sufficiently attenuated, nor properly blended and mixed: the consequence of which will be obstructed perspiration, the habit in general loaded with gross, phlegmatic, and serous humours, and the ossific matter not united or condensed as in an healthy state.

From this debility and laxity of the solids, and consequent viscosity and lentor of the fluids, the rickets are produced; and, from what has been remarked, we may account for the largeness of the brain, liver, and spleen, and the swelled belly, the distortion of the vertebræ and pelvis, contracted thorax, and curvature of the extremities.

The method of cure confirms us likewise in the cause of these symptoms; for, by strengthening the fibrous system, by using gentle exercise, a dry diet, good air, aromatics, and cold bathing, this kind of invalids are generally restored to health.

326
Of the palsy of the lower extremities with curvature of the spine.

Among the diseases of the bones we may likewise take notice of that *palsy of the lower extremities* which takes place, as is generally supposed, in consequence of a curvature in some part of the spine. To this distemper both sexes and all ages are equally liable. When it attacks an infant of only a year or two old or under, the true cause of it is seldom discovered until some time after the effect has taken place. The child is said to be uncommonly backward in the use of his legs, or it is thought to have received some hurt in the birth. When the child is of an age sufficient to have already walked, and who has been able to walk, the loss of the use of his legs is gradual, though in general not very slow. He at first complains of being very soon tired, is languid, listless, and unwilling to move much or at all briskly. Soon after this he may be observed frequently to trip and stumble, though there be no impediment in his way; and whenever he attempts to move briskly, he finds that his legs involuntarily cross each other, by which he is frequently thrown down without stumbling; and when he endeavours to stand still in an erect posture without support, even for a few minutes, his knees give way and bend forward. As the distemper advances, it will be found that he cannot, without much difficulty and deliberation, direct either of his feet exactly to any one point; and very soon after this, both legs and thighs

lose a good deal of their natural sensibility, and become quite useless. In adults, the progress of the disease is much quicker, but the symptoms nearly the same.

Until the curvature of the spine is discovered, the complaint generally passes for a nervous one; but when the state of the back-bone is adverted to, recourse is almost always had to some previous violence to account for it. That this might have been the case in some few instances, might be admitted; but in by far the greatest number some predisposing cause must be looked for.

Mr Pott, who has written a treatise upon this disease, recommends it to our observation, that though the lower limbs are rendered almost useless, or even entirely so, yet there are some circumstances in which it differs from a common nervous palsy. The legs and thighs, though so much affected, have neither the flabby feel of a truly paralytic limb; nor have they that seeming looseness at the joints, nor the total incapacity of resistance which allows the latter to be twisted almost in all directions: on the contrary, the joints have frequently a considerable degree of stiffness, particularly the ankles; by which stiffness the feet of children are generally pointed downward, and they are prevented from setting them flat upon the ground.

The curvature of the spine, which is supposed to be the cause of the complaint, and with which it is always accompanied, is various in situation, extent, and degree, being either in the neck or back, and sometimes, though very seldom, in the upper part of the loins. Sometimes it comprehends only two vertebræ, sometimes three or more, by which the extent of the curve necessarily becomes more or less; but whatever may be the number of the vertebræ concerned, or whatever may be the degree of curvature, our author never saw the arms affected.

When a weak infant is the subject of this disorder, and the curvature is situated in the vertebræ of the back, it is not uncommon for the whole back to become what is called *humped*, at the same time that the bones of the thorax are considerably altered; whence such persons are justly said to be shortened in their stature; but in all cases where this effect has been gradually produced, the curvature of the spine is always the first of these deformities which makes its appearance.

Before the curvature of the spine is discovered, or while no attention is paid to it, the complaint is, as we have already said, looked upon to be nervous; such internals as are supposed to be proper in nervous cases are given, together with warm liniments, embrocations, and blisters, to the part affected: and when the true cause is known, recourse is always had to steel flays, the swing, screw-chair, and other pieces of machinery. But all these are productive of no real or permanent good; the patient becomes unhealthy, and, languishing for some time under a variety of complaints, dies in an emaciated state, or drags on a miserable existence, confined to a great chair or bed, totally deprived of the power of locomotion, and useless both to himself and others.

At first the general health of the patient seems not to be at all, or at least not materially, affected; but when the disease has continued for some time, and the

327
Differences between this and a common palsy.

328
Of the curvature of the spine in this disease.

Theory.

curvature is thereby increased, many inconveniences and complaints come on; such as difficulty in respiration, indigestion, pain, and what they call *tightness at the stomach*, obstinate constipations, purgings, involuntary flux of urine and faeces, &c. with the addition of some nervous complaints, which are partly caused by the alterations made in the form of the cavity of the thorax, and partly by impressions made on the abdominal viscera.

339
Not the
original
cause of the
disorder.

Mr Pott was led to a knowledge of the true cause and cure of this distemper, from observing the case of a youth of 14, who was restored to the use of his limbs immediately after a seemingly accidental abscess near the part. From this he was inclined to think, that the curvature of the spine was not the original cause of the disorder, but that the surrounding parts were predisposed towards it by some affection of the solids and fluids there. For these suspicions he had the following reasons:

1. That he had never seen this paralytic effect on the legs from a mal-formation of the spine, however crooked such mal-formation might have rendered it, or whether such crookedness had been from the time of birth, or had come on at any time afterwards during infancy.
2. That none of those strange twists and deviations, which the majority of European women get in their shapes from the very absurd custom of dressing them in stays during their infancy, and which put them into all directions but the right, ever caused any thing of this kind, however great the deformity might be.
3. That the curvature of the spine, which is accompanied by this affection of the limbs, whatever may be its degree or extent, is at first almost always the same, that is, it is always from within, outward, and seldom or never to either side.
4. That since he had been particularly attentive to the disorder, he had remarked, that neither the degree nor the extent of the curve made any alteration in the nature or degree of the symptoms at first, nor for some time after the appearance; or, in other words, that the smallest curvature, in which only two or three of the vertebræ were concerned, was always at first attended by the same symptoms as the largest.
5. That although it sometimes happened that a smart blow, or a violent strain, had immediately preceded the appearance of the curve, and might be supposed to have given rise to it; yet in many more adults it happened that no such cause was fairly assignable, and that they began to stoop and to falter in their walking, before they thought at all of their back, or of any violence offered to it.
6. That exactly the same symptoms are found in infants, and in young children, who have not exerted themselves, nor have been injured by others, as in the adult who has strained himself or received a blow; and that the case was still the same in those grown people who have neither done nor suffered any act of violence.
7. That although it must be allowed that a dislocation of any of the vertebræ would most probably be attended with the same kind of symptoms from the

pressure it must make on the spinal marrow, yet it is also most probable, that such symptoms would be immediate, and attended with great pain in the part; neither of which is in general the case here.

"These considerations (says he) appeared to me to have much force; but what confirmed me in my opinion was the state of the parts forming the curvature, and which I had several fair opportunities of examining after death. By these examinations I found, in infants, in young children, and in those who had been afflicted with the disorder but a small space of time, that the ligaments connecting the vertebræ which formed the curve, were in some degree altered from a natural state, by being somewhat thickened and relaxed; and that what are called the bodies of those bones, were palpably spread and enlarged in their texture, just as the bones forming the articulations are in children who are called *rickety*. That in those who had long laboured under the distemper, and in whom the symptoms were aggravated, whatever might be their age, the ligaments were still more thickened, relaxed, and altered; the bodies of the bones more spread, more enlarged, and more inclining to become carious; and the cartilages between the bodies of the vertebræ much compressed and lessened in size: and that in all those who had so long laboured under the disease, as to have been destroyed by it or by its consequences, the corpora vertebrarum were completely carious, the intervening cartilages totally destroyed, and a quantity of sanies lodged between the rotten bones and the membranes investing the spinal marrow (A).

"All these circumstances put together, induced me, as I have already said, to suspect, that when we attribute the whole of this mischief to the mere accidental curvature of the spine, in consequence of violence, we mistake an effect for a cause; and that previous both to the paralytic state of the legs, and to the alteration of the figure of the back-bone, there is a predisposing cause of both, consisting in a disordered state of the ligaments and bones, where the curve soon after makes its appearance.

"While the subject was fresh in my mind, I happened to be at Worcester; and in a conversation on it with the late Dr Cameron of that place, I mentioned to him my opinion and my doubts. The doctor concurred with me; and at the same time mentioned a circumstance which made a strong impression on me. He said, that he remembered, some years ago, to have noted a passage in Hippocrates, in which he speaks of a paralysis of the lower limbs being cured by an abscess in the back or loins; and that, taking the hint from this, he, Dr Cameron, had, in a case of a palsy of the legs and thighs, attended by a curvature of the back-bone, endeavoured to imitate this act of nature, by exciting a discharge near the part; and that it had proved very advantageous. He also referred me to Mr Jeffrys, a surgeon of eminence at Worcester, for a farther account of the same kind of attempt. This gentleman confirmed what Dr Cameron had told me; and assured me that he had found the method equally successful.

It

(A) In the body of a man who died not long since of this disorder in its last and worst state, the bodies of three of the vertebræ were not only quite carious, but completely separated from all connection with the other parts of the same vertebræ.

331
Cases of the
dilemper,
by Mr Pott

It may easily be supposed, that these accounts, from gentlemen of veracity, and of reputation in their profession, still added to my desire of knowing more on this subject, and determined me to lose no opportunity of getting information.

"The first that offered was an infant, whose curvature was in the middle of the neck, and who had lost the use of its legs for about two or three months. I made an incise by incision on one side of the projection, and gave strict charge to the mother to take care that the pea was kept in: the woman, who had no faith in the remedy, did not take the proper care; and consequently the discharge was not equal to what it should and might have been: but notwithstanding this neglect, at the end of about three weeks or a month the child was manifestly better, and began to make use of its legs; it was then seized with the small pox, and died. The bodies of the vertebrae concerned in the curve were larger than they should be, and than those above and below were, and their texture much more open and spongy; which difference appeared immediately, before the parts covering them were dissected off.

"Some time passed before I had another opportunity. My next patient was a tall thin man, about 35 years old, who thought that he had hurt himself by lifting a heavy weight. His legs and thighs were cold, and what he called *nummy*, but not absolutely useless: he could with difficulty go about the room with the help of a pair of crutches; but he could neither rise from his chair, nor get on his crutches, without the assistance of another person, nor could he without them walk at all.

"I made a seton on each side of the curve which was in his back, about the middle; and having given his wife directions how to dress them, I called on him once in three or four days. At the end of six weeks he had recovered the due degree of sensation in his limbs, and found much less necessity for the use of his crutches. He could rise from his bed and from his chair without assistance: and, by means of one crutch and an underhand stick, could walk for an hour or more without resting and without fatigue. The setons had now, from not having been properly managed, worn their way out; and I would have converted each of them into an issue: but as neither the patient nor his wife had ever believed that the discharge had had any share in his amendment, but, on the contrary, that he would have been better without it, he would not submit to what I proposed, and I left him. At the distance of about three weeks from the time of my leaving him, I met him in the street walking very stoutly with a common cane, of which he made little or no use. I asked him what he had done: He told me that the sores had continued to discharge till within a few days; but that he had drank a great deal of comfrey-root tea with singlafs; and he supposed that had cured him.

"I believe that the cure of this man will, by all who know any thing of medicine, be thought to be so unlikely to have been effected by the comfrey and singlafs, that my inference in favour of the seton will not be thought unreasonable, and that my determination to prosecute the method, from what I had heard and seen, was well founded.

"Within the course of the last ten or twelve months,

I have had several fair opportunities of doing this, both in St Bartholomew's hospital and out of it; and am very happy to be able to say, that it has not only always answered, but in most instances greatly exceeded, my most sanguine expectations, by restoring several most miserable and totally helpless people to the use of their limbs, and to a capacity of enjoying life themselves, as well as of being useful to others.

"I have now in the hospital a boy about 12 years old, whose case was so truly deplorable, that I made the experiment merely to avoid the appearance of inhumanity by discharging him as incurable without trying something. The curvature was in his back, and consisted of three or four vertebrae; but by means of the weakness thereby induced, the whole set of dorsal ones had so universally and gradually given way, that he was exceedingly deformed both behind and before: he was so absolutely incapable of motion, that he could neither turn himself nor sit up in his bed: his feet were pointed downwards, and his ankles so stiff, that, when he was held up under the arms, the extremities of his great toes touched the floor, nor could his feet be brought flat to the ground by any means or force whatever. In short, he was as perfectly and as totally helpless as can be supposed; and at the same time in an exceeding general bad state of health, from disorders of the thoracic and abdominal viscera. In this state he had been more than a year. It is now about three months since the caustics were applied: he is become healthy, and free from most of his general complaints: has the most perfect use of his legs while he is in bed; can walk without the assistance of any body, or any thing to hold by; and from his manner of executing this, will, I make no doubt, in a very short space, recover perfectly the use of his legs. To this I ought to add, that notwithstanding a considerable degree of deformity does, and I suppose will remain, yet the spine in general is so much strengthened, that he is some inches taller than he was four months ago.

"The remedy for this most dreadful disease consists merely in procuring a large discharge of matter, ³³² His method of cure. by suppuration, from underneath the *membrana adiposa* on each side of the curvature, and in maintaining such discharge until the patient shall have perfectly recovered the use of his legs. To accomplish this purpose, I have made use of different means, such as setons, issues made by incision, and issues made by caustic; and although there be no very material difference, I do upon the whole prefer the last. A seton is a painful and a nasty thing: besides which, it frequently wears through the skin before the end for which it was made can be accomplished. Issues made by incision, if they be large enough for the intended purpose, are apt to become inflamed, and to be very troublesome before they come to suppuration; but openings made by caustic are not in general liable to any of these inconveniences, at least not so frequently, nor in the same degree: they are neither so troublesome to make or maintain. I make the eschars about this size and shape on each side the curve, taking care to leave a sufficient portion of skin between them. In a few days, when the eschar begins to loosen and separate, I cut out all the middle, and put into

each.

Theory.

Theory.

each a large kidney-bean: when the bottoms of the fores are become clean by suppuration, I sprinkle, every third or fourth day, a small quantity of finely-powdered cantharides on them, by which the fores are prevented from contracting, the discharge increased, and possibly other benefit obtained. The issues I keep open until the cure is complete; that is, until the patient recovers perfectly the use of his legs, or even for some time longer: and I should think that it would be more prudent to heal only one of them first, keeping the other open for some time; that is, not only until the patient can walk, but until he can walk firmly, briskly, and without the assistance of a stick; until he can stand quite upright, and has recovered all the height which the habit, or rather the necessity, of stooping, occasioned by the distemper, had made him lose."

SECT. VIII. *Of the different Operations in Surgery, and in what Cases they are proper.*

THE most simple operations are those in which there are neither arteries to tie up, fractures to reduce, nor any divided parts to conjoin by future. They are chiefly phlebotomy or blood-letting; simple incisions into abscesses in order to discharge the matter; and drawing of teeth.——Phlebotomy is useful in all cases where there is a great tendency to inflammation, or where one particular part of the body has been accidentally so much weakened that it cannot bear the impetus of the fluids moving through it with their usual velocity. Hence it is useful in all large wounds, fractures, or contusions, because the impetus of the blood and other fluids, in such cases, is too great to be borne by the weakened and distracted vessels; and if they are entirely divided, it would keep them perpetually bleeding. Hence phlebotomy is also of use in restraining profuse hæmorrhages from any part of the body. On the other hand, it is exceedingly hurtful where the crasis of the fluids tends to a dissolution, or where the vital powers are so weakened that they cannot propel the humours with their usual degree of force. In cases of scurvy, therefore, bleeding is prejudicial; in mortifications, or in large suppurations; because thus the vital powers, which are already reduced, become still more weak, the scorbutic disposition is increased, or the pus cannot be formed as it ought to be. For the same reason, in the lues venerea, however it might seem to be indicated by the pain and swellings, it is entirely improper. The same may be said of all other eruptive disorders, even the itch: for though some have a notion of the good effects of bleeding in this disease, it is always evidently the worse for it; and it will constantly be found, that even this disease proceeds from such causes as weaken the vital powers, such as nastiness, damp, and poor low diet; while, on the other hand, those who keep themselves clean, and live on wholesome strengthening food, are seldom or never troubled with it.

Phlebotomy may be performed in many different parts of the body; and it is found to be more effectual when performed in the neighbourhood of an affected place than at a distance from it. Where the affection of the system is general, bleeding in the arm is most eligible; but if the head or throat are affected, bleeding in the jugular vein is preferable. In

swellings and inflammations of the throat, it will also be of service to open the sublingual veins: in suppurations of the meninges, bleeding in the ankle is recommended: and it has been found in some cases necessary to perform the operation even on the veins of the penis and eyes.

Cupping, with or without scarification, is a kind of partial phlebotomy. Dry-cupping brings a flux and leeches of all the humours towards that part on which the cupping-glass is applied; and hence is useful in bringing the milk towards the breasts of women, in hastening suppuration, &c. If scarification is used, it discharges the blood not only from the small cutaneous veins, but also from the arteries. Hence it is of service in local inflammations.—In the same cases also the application of leeches is useful.

Incision, or something equivalent to it, is always necessary in the case of abscesses, or large collections of matter which cannot otherwise be discharged: tho' large incisions are to be avoided as much as possible; both on account of their evident cruelty, and because they are apt to produce an absorption of matter, and occasion a hectic. In cases of white swellings and cancerous tumours, they ought always to be avoided as much as possible, unless with a view totally to extirpate the diseased parts. On the other hand, in cases of punctured nerves and tendons, incision is not only necessary, but frequently the only means of preserving the patient from death.

Under the head of incision we may likewise reckon the putting in of issues and setons, though the former are more commonly put in by caustic. They are useful in drawing off collections of matter, when situated in such places that they cannot be opened. They are also of use in the case of palsy of the lower extremities with curvature of the spines, as has been already explained, n^o 332. In apoplexies, palsies, and other disorders of the head, they are also frequently of eminent service.

Under the article MEDICINE, n^o 314. it is observed, that where the teeth are carious, the only remedy is to draw them out. However, we are not therefore to imagine, that in all cases of toothach, even when the pain is very severe, that we are to have recourse to this remedy. The teeth are never known to exfoliate, and grow up again, as other bones will do; and therefore the preservation of them is well worthy our attention. But when, by the gradual putrefaction of a tooth, the patient is kept in continual pain, and there is danger of a caries, by means of the affection of the tooth, taking place in the jaw-bone, tooth-drawing then becomes absolutely necessary, and is generally attended with little pain to the patient, as in such cases the teeth are generally loosened in their sockets. It must be remembered, however, that the upper teeth are much worse to draw than the under ones, being not only much faster in their sockets, but connected in such a manner with the nerves of the eyes, especially those called the eye-teeth, as makes the drawing of them very dangerous.

Of the more difficult operations in surgery, the first is future; which necessarily takes place in all cases where we desire the union of parts that would otherwise remain at too great a distance, or where we want to form an adhesion which would not take place naturally. Hence

337
Tooth
drawing.

338
Of futures,

it

Theory. it is necessary in all wounds made in the fleshy parts, and attended with considerable gaping of the lips. It is also necessary in wounds of the abdominal viscera, where they are protruded; in wounds of the aspera arteria, of the oesophagus; in mortifications of the intestines, in order to make the edge of the intestine adhere to the wound; in the hare-lip, &c.

339
Ligature of
arteries.

Under this article likewise we may include the ligature of arteries, which must necessarily take place in all cases where these vessels are wounded, either accidentally or by design, as in the amputation of limbs; and to the same we may refer the operation for aneurisms to be afterwards described, and which seems to be the only method of treating these tumours with any probability of success.

340
Reduction
of fractures,
&c.

Reduction of fractured and dislocated bones ought always to be attempted in case of such accidents, unless where the bones are broken into such small pieces that there can be no hope either of their uniting or of preserving the limb.

341
Amputation.

Amputation is necessary only in such cases as those already mentioned, namely, where, either by external accident, or from some internal cause, the limbs cannot by any means be preserved. Hence it is useful only in those diseases which are plainly destructive of life by the infectious matter absorbed, or where the parts are entirely mortified and useless.

342
Trepan-
ning.

Trepanning of the cranium ought to take place in all cases where there are symptoms of an oppressed brain, provided we have any indication of the place under which the mischief lies, as has already been explained, n° 131. An operation of a similar kind may also upon some occasions be necessary on other bones, in order to remove a part of their carious substance.

343
Of the pa-
ra-centesis.

In cases of dropsy, of hydrocele, empyema, and hydrothorax, the operation called *para-centesis*, or tapping, ought to take place, if the water can be dissipated by no other means. Some collections of water, however, there are, in which this operation is highly

improper, and indeed fatal; such as the hydrocephalus and hydrorachitis, spina bifida, or collection of aqueous fluid in the cavity of the spine. In this last case the spinal marrow is compressed, and all the lower parts of the body become paralytic. The evacuation of this water is certain death; and if any hope remains, it must be by making use of such internal remedies as are mentioned under the article *MEDICINE*, n° 370, for the hydrocephalus.

344
Operations
for the
hernia.

The operation for the bubonocoele, or strangulated hernia, is not to be performed on patients until after every method of reducing the gut has been attempted in vain. It is very fatal, in this country, but much less so in France; but whether owing to any peculiarity in the climate of that country, or to the superior dexterity of the French surgeons, is unknown. An operation of the same nature is sometimes performed in case of a volvulus of the intestines: and it has even been recommended in case of indurated faeces, or balls choking up their cavity; though, as the signs of these are at least but equivocal, we have not heard of any operators so bold as to attempt them.

345
Of lithoto-
my, &c.

One of the most capital operations in surgery is that of lithotomy, or cutting for the stone. This has been practised from the early ages of medicine, but has received great improvements in modern times. Before it is attempted, all possible means should be used for dissolving the stone by the solvents proposed under the article *MEDICINE*, n° 486. However, the operation may be safely performed on persons of all ages; and though many have died under it, many have also survived, and been by it recovered from the most miserable state imaginable to perfect health.

Besides these, there are several other operations in surgery which are connected with particular diseases, and without which these disorders cannot be cured; such as the operation for the fistula lachrymalis, for the cataract, for the fistula in ano, for the phymosis, paraphimosis, &c. all of which shall be described under their proper heads.

PART III. PRACTICE OF SURGERY.

Practice.

THIS consists in performing of the different operations in surgery, in such cases and with such intentions as are most proper; for which last the directions of a physician are often thought necessary; though, as before observed, it were much better that surgeons were themselves acquainted with the cases where manual operations are necessary, and when they are not.—We shall begin with these operations which are most simple and easily performed.

SECT. I. Of Blood-letting.

346
General
rules re-
specting
phlebot-
omy.

THERE are some general rules and observations which relate equally to this operation in whatever part of the body it is practised; these we shall in the first place enumerate with as much accuracy as possible, and shall afterwards proceed to treat particularly of blood-letting in the arm and other parts.

I. In this, as in every other operation, the situation of the patient, and of the operator likewise, ought to be precisely fixed. As the situation of a patient during the operation of blood-letting, has a considerable

influence on the effects produced by the evacuation upon the system, this circumstance therefore merits our particular attention. In some disorders, it is the object of this remedy, to evacuate a considerable quantity of blood without inducing fainting: When this is the case, and when from former experience it is known that the patient to be operated upon is liable during the evacuation to fall into a faintish state, a horizontal posture, either upon a bed or on a couch, ought to be preferred to every other; for every practitioner is now well-acquainted with this fact, that fainting is not near so ready to occur in a horizontal as in an erect posture.

It now and then happens, however, that one ma-
terial advantage expected from the operation of blood-
letting, is the production of a state of deliquium; as, for instance, in cases of strangulated hernia, where a
general relaxation of the system is sometimes desirable.
In all such circumstances, instead of a horizontal
posture, the more erect the patient is kept, the more
readily will a state of fainting be induced: So that

Practice.

347
Of the dif-
ferent pos-
tures to be
assumed by
the patient
before bleed-
ing.

Practice.

Practice.

the particular object in view from the operation must at all times determine this matter.

While we thus, however, attend particularly to the posture of the body at large, the particular position of the limb or part to be operated upon must not be neglected. In every operation it is a matter of much importance to have the patient seated in a proper light, but in none is it more material than in blood-letting. The best general rule that can be given upon this point is, that the patient ought to be so placed, as that the principal light of the apartment shall fall directly upon the part to be operated upon, so that the vein to be opened may be made as apparent as possible.

348
Of the po-
sure of the
operator.

But, whatever may be the position of the part to be operated upon, and whether the patient is to be placed on a bed or on a chair, according to Mr Bell, the surgeon ought always to be seated. The operation may, no doubt, be done while the surgeon is standing; and it is most frequently indeed performed in this manner: But it can never be done either with such steadiness or neatness, as when the operator is firmly seated on a chair.

II. From the coats of veins being more flaccid than those of arteries, and from the blood not proceeding with such rapidity in the former as in the latter, an opening made in one of these will seldom discharge blood freely, unless the vein is either cut entirely across, which in general would be productive of disagreeable consequences, or that the blood be prevented from returning to the heart, by means of a ligature placed between the heart and that part of the vein in which the opening is to be made.

349
Of com-
pressing the
vein.

The patient being properly seated, the next step, in every operation of this kind, must therefore be, by means of a proper bandage, so to compress the vein intended to be opened, as to prevent the blood from returning to the heart; and, for the same reason, an equal degree of pressure, it is obvious, ought to be applied to all the other veins of the part: for if this circumstance should not be attended to, the communication preserved by the collateral corresponding branches would render the pressure upon any one particular vein of very little importance. But, independent of its producing a more free discharge of blood than could be otherwise obtained, this pressure upon the veins, by inducing an accumulation of their contents, tends to bring them more evidently into view, and consequently renders it easier for the operator to to effect a proper opening than he would otherwise find it.

Although compression, however, to a certain extent, is necessary for this purpose of accumulating a quantity of blood in the veins, and for afterwards discharging it at an opening made by the lancet, it is at the same time perfectly evident, that any considerable degree of pressure, instead of forwarding these purposes, must obstruct them entirely: for if the pressure intended to be applied to the veins only, should accidentally be carried so far as to rest materially upon the arteries connected with them, all farther access of blood to the veins would be thereby cut off, so that no evacuation of importance could take place at any opening to be made in them. Whenever it is intended, therefore, to evacuate blood in this manner,

a good deal of nicety is requisite in applying this pressure upon the veins: it ought always to be carried so far as effectually to compress the veins of the part, but never to such a degree as to obstruct the circulation in the corresponding arteries. When we see that the pressure applied has the effect of raising the veins, and if at the same time the pulsation of the artery is distinctly felt in the inferior part of the member, we may then be certain that it is to a very proper degree, and that it ought not to be carried farther: for by the swelling of the veins we are sure that they are sufficiently compressed; and by the arteries continuing to beat, it is evident that a continued flow of blood may be expected.

III. The reflux of blood to the heart being in this manner prevented, the next question to be determined is, the best method of making an opening into the vein. Different instruments have been invented for this purpose; but there are two only which have been retained in use, and which are all, therefore, that here require to be mentioned. These are the lancet and the phlegm. This last, on being placed immediately on the part to be cut, is, by means of a spring, pushed suddenly into the vein, and produces an opening of the exact size of the instrument employed.

The phlegm, in many parts of Germany, has acquired some reputation, particularly in taking blood from the jugular vein: but there are various objections to the use of this instrument, which must undoubtedly prevent it from ever coming into general use; and these particularly are, that we are obliged, from the nature of the instrument, to regulate the deepness to which it is to go before it is applied. Now we know well, that in blood-letting this is a circumstance we are never by any means certain of: for we frequently, after the introduction of a lancet, find it necessary to go much deeper than was at first expected; so that when a phlegm is used, unless we employ one on every occasion of a length which cannot be frequently required, we must often meet with disappointments.

But the most material objection to this instrument is, that where there are arteries or other parts lying below the veins, and in any danger of being hurt by the operation of blood-letting, the risk is much greater with the phlegm than with the lancet. For when the lancet is used, after the vein is once opened, the orifice may be enlarged at pleasure without any additional risk, merely by carrying the instrument forward along the course of the vein in the same depth to which it was at first introduced: whereas with the phlegm, so soon as it enters the vein, it must for certain pass directly downwards to its full length; a circumstance which adds greatly to the risk of wounding the parts underneath.

Independent of this, too, by the use of the lancet, we have it much more in our power to command an orifice of a determined size than when the phlegm is used: So that, without hesitation, we may venture to pronounce the phlegm to be an instrument in no degree necessary.

The broad-shouldered lancet in ordinary use, is an instrument which ought to be laid entirely aside. For opening abscesses it is very well calculated; but for the operation of blood-letting, it ought never to be used. The capital objection to this kind of lancet is, that

350

the open-
ing.

351

scribed.

352
Of the pro-
per form of
lancets.

that the broadness of its shoulders produces always a wound in the external teguments of perhaps three times the size of the opening made in the vein; a circumstance which adds no advantage whatever to the operation; on the contrary, it produces much unnecessary pain in the first instance; it renders it frequently a very difficult matter to command a stoppage of the blood; and the wounds produced by it are commonly so extensive, as to render them very liable to terminate in partial suppurations; an occurrence which always proves painful and disagreeable to the patient.

The spear-pointed lancet, on the contrary, is an instrument in every respect well calculated for the purpose of venæsection. From the acuteness of its point, it enters the teguments and vein with very little pain; which, we may here observe, is with many patients a circumstance of no small importance. We are sure of making the opening in the vein equal, or nearly so, to the orifice in the external teguments; and the discharge of blood produced by an opening made with one of these lancets, is commonly put a stop to with great ease, immediately on removing the ligature upon the vein.

"For these reasons, therefore, (says Mr Bell), the spear-pointed lancet is highly preferable to every other. And although, with timid practitioners, the acute point of this instrument may appear to require more dexterity in using it than the broad-shouldered lancet; yet the difference in this respect is so inconsiderable, that a very little experience of its excellency must, with every practitioner who gives it a fair trial, soon counterbalance all such objections. Indeed, no surgeon ought to be trusted in letting blood with the one, whose steadiness and dexterity would be in any degree doubted with the other."

IV. The form of lancet being thus fixed upon, we come now to speak of the method of using it. The surgeon and patient being both properly seated, and the ligature having been applied for a short space of time in order to produce some degree of swelling in the veins, that vein is to be made choice of which, at the same time that it appears conspicuously enough, is found to roll less than the others on being pressed upon by the fingers. There are some veins which roll so much, from being loose and unconnected with the cellular substance of the part, that although they may rise sufficiently, yet are much worse to operate upon than others which lie at a much greater depth. That vein therefore is to be preferred, which not only rises so as to become perfectly evident, but which appears to be connected with some degree of firmness to the contiguous parts. It is scarcely thought necessary to observe here, that when a vein appears to be so immediately connected with a contiguous artery or tendon, as evidently to produce some risk of wounding these parts in the operation, another vein not liable to such hazard, if it can be procured, ought undoubtedly to be preferred.

Veins may lie directly above both arteries and tendons, and yet no manner of risk be incurred by opening them, provided the operator is sufficiently steady and attentive; but it does now and then happen, that veins are so nearly and intimately connected with these

Vol. X.

parts, as to render it hazardous even for the most dexterous surgeon to attempt this operation.

The vein being at last made choice of, the surgeon, if he is to use his right-hand in the operation, takes a firm hold of the member from whence the blood is to be drawn with his left, and, with the thumb of the same hand, he is now to make such a degree of pressure upon the vein, about an inch and half below the ligature, as not only to render the skin and teguments somewhat tense, but at the same time to interrupt for a little all communication between the under part of the vein and that portion of it lying between the ligature and the thumb placed as thus directed.

The lancet being bent to somewhat more than right angles, the operator now takes it between the finger and thumb of his right-hand; and leaving at least one half of the blade uncovered, he rests his hand on the middle finger, ring-finger, and little finger, all placed as conveniently as possible in the neighbourhood of the vein from whence the blood is to be taken; and having pushed the point of the instrument freely through the skin and teguments into the vein, he now carries it forward in an oblique direction, till the orifice is of the size he inclines to have it; taking care, during the time of pushing on the lancet, that its point be kept in as straight a direction as possible, for fear of dipping into the parts below.

The instrument is now to be withdrawn; and the surgeon, removing the thumb of his left hand, is to allow the vein to empty itself freely into the different cups previously provided for the purpose.

It is here of importance to observe, that during the time the blood is discharging, the member ought to ³⁵⁶ Of the posture of the limb. be kept in exactly the same posture it was in when the lancet was first introduced: otherwise the orifice in the skin is apt to slip over the opening in the vein; a circumstance which always proves inconvenient, and on some occasions produces a good deal of trouble by the blood from the vein insinuating itself into the surrounding cellular substance.

In taking hold of the lancet, we have directed the scales to form rather an oblique angle with the blade of the instrument. It will answer when they are even at right angles; but a farther separation proves always troublesome, by throwing the scales too much out upon the operator's hand. The length of instrument left out from between the finger and thumb is another circumstance requiring our attention; for unless a sufficient quantity of it is left uncovered, the operator cannot act with freedom. In lancets of an ordinary length, one half of the blade, or very nearly that quantity, ought always to be left out.

The entry of the lancet into the vein is the next circumstance we have desired to be attended to. By very little attention, the entrance of the instrument into the vein may be distinctly perceived: for so soon as its point has entered the cavity of the vessel, the resistance to its farther progress is evidently found to be much diminished; and immediately on the opening being in any degree enlarged, the blood begins to rush out; which is the clearest proof of the operation being so far complete. On being thus rendered sure that the lancet has got into the vein, we have also desired that it may be carried forward in an oblique

Practice.

direction, taking care to keep the point of the instrument in the same degree of elevation from the instant it has passed fairly through the coats of the vein; and to this part of the operation the most particular attention ought to be given. To the want of necessary caution in this matter, or rather to the improper regulations held forth upon it by every writer on this subject, much of the risk attending this operation ought to be attributed.

357
Why the
Orifice
should be
oblique.

The propriety of an oblique direction for the course of the orifice is very obvious: for when made altogether longitudinal, the sides of the wound are apt to fall immediately together, so as not to admit of a free discharge of blood; and, on the other hand, when the vein is cut entirely across, troublesome consequences commonly ensue from the wound being very difficult to heal. An orifice somewhat oblique with respect to the course of the vein, is therefore preferable to either. But the material circumstance to be kept in view, is the direction of the point of the lancet after it has got fairly into the vein.

The reason of this last precaution is, that the internal orifice of the vein may not be farther extended upwards than the external wound in the skin and other teguments, as ecchymoses, or effusions of blood into the cellular substance, have, with the broad-shouldered lancet, been found frequently to occur from a contrary management. But when the spear-pointed lancet is used, this is an occurrence which need never happen; as, from the narrow point of the instrument, it may with safety be carried on in the cavity of the vein as far as is necessary. The orifice produced by it in the vein must, when the operation is properly done, be always of very nearly the same extent as the external wound in the teguments: and, by the same management, we avoid that capital risk which it is evident must always occur from an implicit obedience to the direction alluded to; for one certain effect of raising the heel or back-part of the lancet, is, that the point of the instrument must in the same proportion be depressed; and the consequence of lowering the point of the lancet, already perhaps sliding along the under side of the vein, must at once appear to be very hazardous: for, in such circumstances, if the point of the instrument be depressed, which must undoubtedly happen if the back-part of it be elevated, it must for certain pass through the back-part of the vein; so that if either an artery, nerve, or tendon, lie contiguous, they must of necessity be wounded: and we are perfectly convinced, that this cause alone has frequently been the origin both of wounded arteries and of pricks in the nerves and tendons. So that as the hazard of the practice, whenever it is attentively considered, must at once appear evident; and as the supposed inconvenience, arising from a contrary mode of operating, is effectually prevented by the use of the spear-pointed lancet, all such risks therefore should be carefully avoided.

358
Of the size
of the ori-
fice.

With respect to the size of orifice in cases of blood-letting, this circumstance must at all times be determined by the nature of the disorder for which the evacuation is prescribed. When a sudden loss of a considerable quantity of blood is intended, either with a view to produce a state of fainting, or for any other

reason, a free large orifice is absolutely necessary; but in ordinary practice, no necessity occurs for this.

In using a spear-pointed lancet, an orifice of about an eighth part of an inch in length will in general answer every purpose: but when a lancet with broad shoulders is used, an opening of twice that size is little enough; for, with such an instrument, the orifice in the vein can seldom be above half the extent of the external opening.

After withdrawing the lancet from the orifice, we have directed the thumb of the left-hand to be removed from the place it was made to occupy. One material use of the thumb placed below the part where the lancet was directed to enter, is to keep the teguments and vein firm, so as to prevent the latter from rolling. But another advantage occurring from it is, that, by making a sufficient degree of pressure upon the vein, it thereby prevents any considerable quantity of blood from escaping between the time of removing the lancet, and the application of one of the cups for receiving the blood from the orifice in the vein. During this period, it frequently happens that a good deal of blood is discharged, to the great annoyance both of the patient, the operator, and bystanders; a circumstance which, with a little attention, may be always effectually prevented.

V. When the vein is properly cut, and the orifice is made sufficiently large, it rarely occurs that any difficulty is experienced in procuring all the blood that is wanted. But it now and then happens otherwise, either from the orifice of the skin and other parts having receded from the opening in the vein, or from the patient having become faintish; a situation always unfavourable to a free discharge of blood. When this last circumstance occurs, a stream of fresh air ought to be admitted to the apartment, wine or some other cordial should be administered, and the patient ought to be laid into a horizontal posture. By these means the faintness will in general be soon removed: but if still the blood should not flow freely, the member ought to be put into all the variety of positions that can probably assist in bringing the openings of the skin and other teguments to correspond with that of the vein; which will soon be known to have happened by the blood beginning instantly to flow. Throwing the muscles of the part into constant action, by giving the patient a cane or any other firm substance to turn frequently round in his hand when the operation is done in the arm, will often answer in producing a constant flow of blood from a vein, when every other means has failed: And, lastly, when the pulse in the inferior part of the member is felt very feeble, or especially if it cannot be distinguished at all, we may be thereby rendered certain that the ligature is too tight, and may in general have it in our power to produce an immediate flow of blood, by removing the compression thus improperly made upon the arteries of the part.

VI. A quantity of blood proportioned to the nature of the disorder being thus discharged, the pressure upon the superior part of the vein should be immediately removed; and this being done, if the spear-pointed lancet has been used, all farther loss of blood will in general stop immediately. The contrary of this, however, sometimes occurs, and blood continues

359

small a
of blood

360
Of stop-
ping too
flux.

to

to flow freely even after the ligature is removed. When this is the case, the operator ought to compress the vein both above and below the orifice, by means of the finger and thumb of one hand, so as to prevent any farther loss of blood : And this being done, the limb ought to be washed, and entirely cleared of any blood that may have fallen upon it ; and the orifice being also cleared of every particle of blood, the sides of it should be laid as exactly together as possible ; and a piece of court or any other adhesive plaster being so applied as to retain them, it will seldom happen that any kind of bandage is necessary : but when the blood has issued with uncommon violence during the operation, and has been difficult to command after the removal of the ligature, in such instances it will be prudent to apply a small compress of linen over the plaster, and to secure the whole with a linen roller properly applied round the member.

§ 1. Of Venaesection in the Arm.

In applying the ligature for the stoppage of the circulation, it ought to be placed about an inch or an inch and half above the joint of the elbow ; and in order to prevent the ends of it from interfering with the lancet, the knot should be made on the outside of the arm. In general, one knot might answer ; but a slip-knot being made above the first, renders it more secure, and it is very easily done.

In forming the choice of a vein from whence blood is to be taken, the general rules we have already laid down upon this point must be here particularly attended to. That vein which appears most conspicuous, at the same time that it rolls least under the skin, should in general be fixed upon ; but when an artery is found to lie immediately below, and quite contiguous to such a vein, the operator, if he is not perfectly satisfied with his own steadiness, ought rather to take some other. In general, however, the artery lies so low in this place, that the median basilic vein, under which it commonly runs, may be opened with perfect safety ; and as this vein in general appears more conspicuous than any of the others, probably from the continued pulsation of the artery below obstructing in some measure the passage of its contents, it is in this respect, therefore, more properly calculated for this operation than any of the others. Other circumstances occur, too, which render the median basilic preferable to the cephalic or median cephalic veins for the operation of blood-letting. The former, viz. the median basilic, is less deeply covered with cellular substance ; and by lying towards the inner part of the arm, it is more thinly covered with the tendinous expansion of the biceps muscle than either of the others. From these circumstances, the operation is always attended with less pain when done in this vein than in any of the others.

In blood-letting at this part of the arm, although the operation may be done with the right-hand either upon the right or left arm of the patient, yet it is much more neatly done by performing with the right-hand upon the right-arm, and with the left-hand upon the left-arm of the patient.

In very torpid people, it sometimes happens that all the larger veins lie so deep as not to be discovered by the eye ; but when they are sensibly felt by

the fingers, even although they cannot be seen, they may be always opened with freedom. In a few instances, however, they can neither be distinguished by the eye nor by the finger : in such a situation, as they may in general be met with about the wrist, or on the back-part of the hand, the ligature should be removed from the upper part of the arm ; and being applied about half-way between the elbow and wrist, the veins below will thereby be brought into view ; and wherever a vein can be evidently observed, there can be no danger in having recourse to the operation.

§ 2. Of Blood-letting in the jugular Vein.

THERE is only one ramification of this vein, viz. its principal posterior branch, which can easily be brought so much into view as to be with propriety opened ; and even this lies deeply covered with parts, not only with the skin and cellular substance, but with the fibres of the platysma myoides muscle ; so that a considerable degree of pressure becomes necessary in order to raise it to any height. With a view to produce this, the operator's thumb is commonly advised to be placed upon the vein, so as to compress it effectually about an inch or inch and half below where the opening is to be made. This, however, seldom proves sufficient for the purpose, as the blood, on being stopped in its progress through this branch, easily finds a passage to the other veins ; so that unless the principal vein on the other side of the neck is also compressed, the vein to be opened can never be fully distended. In order to effect this, a firm compress of linen should be applied on the largest vein on the opposite side of the neck ; and an ordinary garter, or any other proper ligature, being laid directly over it, should be tied with a firm knot below the opposite arm-pit ; taking king care to make such a degree of pressure, as to put an entire stop to the circulation in the vein, which in this way may be easily effected without producing any obstruction to the patient's breathing.

This being done, and the patient's head properly supported, the operator, with the thumb of his left-hand, is now to make a sufficient pressure upon the vein to be opened ; and with the lancet in his right-hand is to penetrate at once into the vein ; and, before withdrawing the instrument, an orifice should be made large enough for the intended evacuation. It may be proper to observe, that a more extensive opening ought always to be made here than is necessary in the arm, otherwise the quantity of blood is generally procured with difficulty : and besides, there is not the same necessity for caution on this point here that there is in the arm ; for it seldom or never happens, that any difficulty occurs, in this situation, in putting a stop to the blood after the pressure is removed from the veins, all that is commonly necessary for this purpose being a slip of adhesive plaster without any bandage whatever.

In order to bring the vein more clearly into view, so as afterwards to be able to open it with more exactness, it has been recommended, that the skin, cellular substance, and muscular fibres covering the vein, be divided before it is attempted to be pushed into it. There is not, however, any necessity for this precaution, as it rarely

Practice.]

happens that any difficulty is experienced in procuring a free discharge of blood by opening the vein and teguments at once in the manner directed. And it is here, as in every instance where it is necessary to take blood by a lancet, if it is not done at once, the patient is much disappointed, and is sure to attribute the failure entirely to a fault in the operator.

364

§ 3. Of Venesection in the Ankles and Feet.

WHEN blood is to be discharged from the veins of these parts, it will be readily understood, that the first step to be taken is a proper compression of the veins, so as to produce an accumulation of their contents. The ligature for this purpose being applied with a sufficient degree of tightness a little above the ankle-joint, all the branches of the vena saphena, both in the inside and outside of the foot, come at once into view; and as this vein lies every where very superficial, being in general covered with skin only, wherever a proper vein appears conspicuously it may with safety be opened.

With a view to encourage the discharge of blood, it has been a constant practice in blood-letting in these veins, to dip the feet into warm-water immediately on the orifice being made. But this is a very inaccurate method of proceeding, as the quantity of blood taken in this manner can never be ascertained with precision; for the blood being all mixed with the water, the operator can never be in any degree certain as to this point: and besides, there does not appear to be any necessity for this assistance; for when the compression of the superior part of the veins is made effectual, and the orifice is of a proper size, there is seldom more difficulty in obtaining a full discharge of blood from the veins of these parts than from any other veins of the body.

On removing the ligature, the discharge is generally stopped at once; so that a piece of adhesive plaster applied over the orifice, answers all the purpose of a bandage.

365

§ 4. Of blood-letting in the Veins of the Forehead, Temples, and Occiput.

BEFORE proceeding to cut the veins, an handkerchief or neckcloth ought to be drawn tight round the neck; that, by compressing the jugular vein, those branches of it may become more turgid and conspicuous. The vein being opened, the patient must hold down his head, that the blood may not trickle from his forehead into his eyes or mouth, when the stream does not spin out with sufficient force. If the blood does not stop of itself after a due quantity is discharged, you must compress the orifice with your finger; and, after wiping the forehead and face, apply a compress or two, and then your bandage.

366

§ 5. Of Blood-letting in the Veins called Ranulae, under the Tongue.

To bleed in these veins, a stricture being made upon the neck as before, you then elevate the apex of the tongue with your left-hand, while with the lancet in your right you circumspectly open first one and then the other on each side, because the aperture of one only will hardly ever discharge blood enough to give any considerable relief. When you judge a sufficient

Practice]

quantity of blood has run out of the mouth into your vessel, remove the ligature from the neck; upon which the flux usually stops of itself: but if it should still continue, let the patient take a little vinegar or Frontinac wine in his mouth; or else you may apply a bit of vitriol or alum, or a compress dipped in some styptic liquor, till the hæmorrhage ceases; which can never be dangerous even without such topicals.

367

§ 6. Of Venesection in the Penis.

BLEEDING in the vena dorsalis penis usually surpasses the benefit of all remedies whatever in abating inflammatory disorders of this member. This large vein, which runs along the back or upper side of the penis, being generally pretty much distended, and conspicuous in an inflammation of this part, may be incised about the middle or back part of the penis; and kept bleeding till the member becomes flaccid, and a sufficient quantity of blood be discharged proportionable to the urgency of the symptoms. This done, you must apply a compress, and the bandage proper for the penis. But you must carefully endeavour to avoid injuring the arteries or nerves which enter the penis near this vein; as also not to make your bandage too strict; for by these means the inflammation and lymph-toms may turn out worse than before.

When it is found necessary to discharge blood in this manner from the penis, the veins can be easily brought into view, by producing an accumulation of their contents in the same manner as in other parts of the body, through the intervention of a ligature: but in the tongue, in the hæmorrhoidal veins about the anus, and other parts where compression cannot be applied, all that the surgeon can do, is to make an orifice of a proper size in that part of the vein which shows itself most evidently; and if a sufficient discharge of blood is not thus produced, as there is no other method of effecting it, immersing the parts in warm water may in such circumstances be a very necessary measure.

§ 7. Of Venesection in the Eyes.

368]

THERE are several ways of performing this operation, of which we shall here only relate the chief. First, the patient is to be seated conveniently on the bed-side or on a chair, with his head held in a proper posture by an assistant; which done, the surgeon makes a transverse incision with a lancet upon the turgid small veins in the corners of the eye, so as to open them or cut them quite asunder. Some use a small pair of scissors, instead of a lancet, to divide the vessels; but in using either of them, the eye-lids must be held apart from each other by the fingers of one hand, while the vessels are incised by those of the other. Some, again, elevate the small turgid veins with a crooked needle before they divide them, the eye-lids being in the mean time held asunder by an assistant. But it would be still better to have these crooked needles made thin and double-edged, so that they may divide the vessels of themselves in the elevation, without the use of lancet or scissors. The small veins being thus incised or divided, their discharge of blood should be promoted by fomentations of warm water frequently applied to the eye by means of a sponge or soft linen rags.

Among other methods that have been proposed for scarifying

scarifying the blood-vessels of the eye, the beards of rough barley were at one period much extolled, and are still employed by some individuals. By drawing them over the surface of the eye, in a direction contrary to the sharp spiculae with which they are furnished, a considerable discharge of blood is thereby produced: But the pain attending this operation is exquisite; and as it does not possess any superior advantage to the method with the lancet, it is now falling into general disuse.

§ 8. Of Arteriotomy.

WHATEVER particular advantages may in theory have been expected from arteriotomy, and however some of its supporters may have recommended it, not only as being in many instances preferable to venesection, but as an operation perfectly safe even in vessels of considerable size; yet the most strenuous friends to the practice have shrunk from any real attempt of this kind on the larger arteries. Instances have no doubt occurred of large arteries having been opened without any danger ensuing; but these are so exceedingly rare, that no practitioner of experience will, from that consideration, be induced coolly to proceed to open any artery of importance. The smaller branches of arteries may indeed be opened with great safety when they are not deeply covered, and especially when they lie contiguous to bones; as in such situations, so soon as the quantity of blood intended to be taken is discharged, all further loss of blood may be very easily prevented by compression: but in any of the larger arteries, the attempt must be always attended with so much hazard, and the advantages to be expected from it in preference to venesection are apparently so trifling, as must in all probability prevent it from ever being carried into execution.

³⁶⁹
Few arteries can be opened with propriety.

There are very few arteries, therefore, which with any propriety can be opened: the different branches of the temporal are the only arteries indeed from whence blood in ordinary practice is ever taken; but if a fanciful practitioner should at any time incline to take blood in this manner from a different part, it may be done with great safety from one of the arteries running on each side of the fingers. About the middle of the last phalanx, this artery is sufficiently large for discharging a considerable quantity of blood: in most cases it lies very superficial; and in this situation there can seldom much difficulty occur in putting a stop to the evacuation. In performing this operation on any of the temporal branches, if the artery lies superficial, it may be done with one push of the lancet, in the same manner as was directed for venesection; but when the artery lies deeply covered with cellular substance, it is always necessary to lay it fairly open to view, before making the orifice with the lancet: for in all the smaller arteries, when they are cut entirely across, there is little chance of being able to procure any considerable quantity of blood from them; as, when divided in this manner, they are sure to retract considerably within the surrounding parts, which commonly puts a stop to all farther evacuation.

Some degree of nicety is also necessary in making the opening into the artery of a proper oblique direction, neither quite across nor directly longitudinal; for a longitudinal opening never bleeds so freely, ei-

ther in an artery or in a vein, as when its direction is somewhat oblique.

If the opening has been properly made, and if the artery is of any tolerable size, it will at once discharge very freely without any compression; but when the evacuation does not go on so well as could be wished, the discharge may be always assisted by compressing the artery immediately above the orifice, between it and the corresponding veins. The quantity of blood being thus discharged, it will commonly happen, that a very slight compression on these smaller arteries will suffice for putting a stop to the evacuation: and whatever pressure is found necessary, may be here applied in the same manner as was directed in venesection; first, by clearing the orifice entirely of blood; and having covered it properly with a piece of adhesive plaster, if that should not be found to answer, a compress of linen should be applied over it, the whole being then to be secured with a roller.

It happens, however, in some instances, that this does not succeed, the orifice continuing to burst out from time to time, so as to be productive of much distress and inconvenience.

In this situation there are three different methods ³⁷⁰ by which we may with tolerable certainty put a stop ^{Method of} to the farther discharge of blood. 1st, If the artery ^{the blood.} is small, as all the branches of the temporal arteries commonly are, the cutting it entirely across, exactly at the orifice made with the lancet, by allowing it to retract within the surrounding parts, generally puts an immediate stop to the discharge. 2^d, When that is not consented to, we have it always in our power to secure the bleeding vessel with a ligature, as we would do an artery accidentally divided in any part of the body. And, lastly, if neither of these methods is agreed to by the patient, we can, by means of a constant regular pressure, obliterate the cavity of the artery at the place where the operation has been performed, by producing the accretion of its sides. Different bandages have been contrived for compressing the temporal artery; but none of them answer the purpose so easily and so effectually as the one figured in the Plate.

As some time, however, is required to obliterate the cavity of the artery, this method is accordingly more tedious; but to timid patients it generally proves more acceptable than either of the other two.

§ 9. Of Topical Blood-letting.

WHEN, either from the severity of a local fixed pain, or from any other cause, it is wished to evacuate blood directly from the small vessels of the part affected, instead of opening any of the larger arteries or veins, the following are the different modes proposed for effecting it, viz. by means of leeches; by slight scarifications with the shoulder or edge of a lancet; and, lastly, by means of an instrument termed a *scarificator*, in which any number of lancets, from one to twenty or upwards, may be placed, and are fixed in such a manner, that, when the instrument is applied to the part affected, the whole number of lancets contained in it are, by means of a strong spring, pushed suddenly into it, to the depth at which the instrument has been previously regulated. This being done, as the smaller blood-vessels only by this operation are

³⁷¹
Scarificator described.

Practice.

ever intended to be cut, and as these do not commonly discharge freely, some means or other become necessary for promoting the evacuation.

272
Of cupping-
glasses.

Various methods have been proposed for this purpose. Glasses fitted to the form of the affected parts, with a small hole in the bottom of each, were long ago contrived; and these being placed upon the scarified parts, a degree of suction was produced by a person's mouth sufficient for nearly exhausting the air contained in the glass: and this accordingly was a sure enough method of increasing the evacuation of blood to a certain extent. But as this was attended with a good deal of trouble, and besides did not on every occasion prove altogether effectual, an exhausting syringe was at last adapted to the glass: which did indeed answer as a very certain method of extracting the air contained in it; but the application of this instrument for any length of time is very troublesome, and it is difficult to preserve the syringe always airtight.

The application of heat to the *cupping-glasses*, as they are termed, has been found to rarify the air contained in them to a degree sufficient for producing a very considerable suction. And as the instrument in this simple form answers the purpose in view with very little trouble to the operator, and as it is at all times easily obtained, the use of the syringe has therefore been laid aside.

There are different methods adopted for thus applying heat to the cavity of the glass. By supporting the mouth of it for a few seconds above the flame of a taper, the air may be sufficiently rarified; but if the flame is not kept exactly in the middle, but is allowed to touch either the sides or bottom of the glass, it is very apt to make it crack. A more certain, as well as an easier, method of applying the heat, is to dip a piece of soft bibulous paper in spirit of wine; and having set it on fire, to put it into the bottom of the glass, and, on its being nearly extinguished, to apply the mouth of the instrument directly upon the scarified part. This degree of heat, which may be always regulated by the size of the piece of paper, and which it is evident ought to be always in proportion to the size of the glass, if long enough applied, proves always sufficient for rarifying the air very effectually, and at the same time, if done with any manner of caution, never injures the glass in the least.

The glass having been thus applied, if the scarifications have been properly made, they instantly begin to discharge freely: and so soon as the instrument is nearly full of blood, it should be taken away; which may be always easily done by raising one side of it, so as to give access to the external air. When more blood is wished to be taken, the parts should be bathed with warm water; and being made perfectly dry, another glass, exactly of the size of the former, should be instantly applied in the very same manner: and thus, if the scarificator has been made to push to a sufficient depth, so as to have cut all the cutaneous vessels of the part, almost any necessary quantity of blood may be obtained. It sometimes happens, however, that the full quantity intended to be discharged cannot be got at one place. In such a case, the scarificator must be again applied on a part as contiguous to the other as possible; and this being done, the ap-

plication of the glasses must also be renewed as before.

Practice.

When it is wished to discharge the quantity of blood as quickly as possible, two or more glasses may be applied at once on contiguous parts previously scarified; and, on some occasions, the quantity of blood is more quickly obtained by the cupping-glasses being applied for a few seconds upon the parts to be afterwards scarified. The suction produced by the glasses may possibly have some influence in bringing the more deeply seated vessels into nearer contact with the skin, so that more of them will be cut by the scarificator.

A sufficient quantity of blood being procured, the wounds made by the different lancets should be all perfectly cleared of blood; and a bit of soft linen or charpie, dipped in a little milk or cream, applied over the whole, is the only dressing that is necessary. When dry linen is applied, it not only creates more uneasiness to the patient, but renders the wounds more apt to fester than when it has been previously wetted in the manner directed.

Although this operation is by no means difficult in the execution, yet a good deal of practice is necessary to perform it in a neat and successful manner; but, with a little attention, any operator may soon become so expert, as to be able to take any quantity of blood that it can ever be necessary to evacuate.

Dry cupping consists in the application of the cupping-glasses directly to the parts affected, without the use of the scarificator. By this means a tumour is produced upon the part; and where any advantage is to be expected from a determination of blood to a particular spot, it may probably be more easily accomplished by this means than by any other.

373
Dry cupping.

When the part from which it is intended to produce a local evacuation of this kind is so situated, that a scarificator and cupping-glasses can be applied, this method is greatly preferable to every other; but it now and then happens, that parts are so situated as not to admit of their application. Thus, in inflammatory affections of the eye, of the nose, and of other parts of the face, the scarificator cannot be properly applied directly to the parts affected. In such instances, leeches are commonly had recourse to, as they can be placed upon almost any spot from whence we would wish to discharge blood.

In the application of these animals, the most effectual method of making them fix upon a particular spot, is to confine them to the part by means of a small wine-glass. Allowing them to creep upon a dry cloth, or upon a dry board, for a few minutes before application, makes them fix more readily; and moistening the parts on which they are intended to fix, either with milk, cream, or blood, tends also to cause them adhere much more speedily than they otherwise would do. So soon as the leeches have separated, the ordinary method of promoting the discharge of blood, is to cover the parts with linen cloths wet in warm water. In some situations, this may probably be as effectual a method as any other; but wherever the cupping-glasses can be applied over the wounds, they answer the purpose much more effectually; wherever the figure of the part, therefore, will admit of their application, they ought undoubtedly to be employed.

374
Of the application of leeches.

§ 1. Of opening Abscesses.

375
Incision
preferable
to caustic.

THERE are two ways of opening an abscess; either by incision or caustic; but incision is preferable in most cases. In small abscesses, there is seldom a necessity for greater dilatation than a little orifice made with the point of a lancet; and in large ones, where there is not a great quantity of skin discoloured and become thin, an incision to their utmost extent will usually answer the purpose; or if there be much thin discoloured skin, a circular or oval piece of it must be cut away: which operation, if done dexterously with a knife, is much less painful than by caustic, and at once lays open a great space of the abscess, which may be dressed down to the bottom, and the matter of it be freely discharged: whereas, after a caustic, though we make incisions through the eschar, yet the matter will be under some confinement; and we cannot have the advantage of dressing properly till the separation of the slough, which often requires a considerable time, so that the cure must be necessarily delayed: besides that the pain of burning continuing two or three hours, which a caustic usually requires in doing its office, draws such a suction upon the skin round the eschar, as sometimes to indispose it very much for healing afterwards. In the use of caustics, it is but too much a practice to lay a small one on the most prominent part of a large tumour, which not giving sufficient vent to the matter, and perhaps the orifice soon after growing narrow, leads on to the necessity of employing tents; which two circumstances more frequently make fistulas after an abscess, than any malignity in the nature of the abscess itself. The event would more certainly be the same after a small incision: but surgeons, not depending so much on small openings by incision as by caustic, do, when they use the knife, generally dilate sufficiently; whereas, in the other way, a little opening in the most depending part of the tumour usually satisfies them.

376
Advantages
of using
caustic in
some cases.

From this account of the method of opening abscesses, it does not appear often necessary to apply caustics; yet they have their advantages in some respects, and are seldom so terrible to patients as the knife, though in fact they are frequently more painful to bear. They are of most use in cases where the skin is thin and inflamed, and we have reason to think the malignity of the abscess is of that nature as to prevent a quickness of incising; in which circumstance, if an incision only were made through the skin, little sinuses would often form underneath, and the lips of it, lying loose and flabby, would become callous, and retard the cure, though the malignity of the wound were corrected. Of this kind are venereal buboes; which notwithstanding they often do well by mere incision, yet, when the skin is in the state we have supposed, the caustic is always preferable: but this method should be confined to venereal buboes; for those which follow a fever or the small-pox, for the most part are curable by incision only. There are many scrophulous tumours, where the reasoning is the same as in the venereal; and even in great swellings, if the patient will not submit to cutting, and the surgeon is apprehensive of any danger in wounding a large vessel, which is, often done with the knife, but

is avoided by caustic, it may on such an occasion be made use of; however, in scrophulous swellings of the neck and face, unless they are very large, caustics are not advisable, since in that part of the body, with length of time, they heal after incision.

When an abscess is ready burst, we are to be guided by the probe where to dilate, observing the same rules with regard to the degree of dilatation as in the other case. The usual method of dilating, is with the probe-scissars; and indeed, in all abscesses, the generality of surgeons use the scissars, after having first made a puncture with a lancet: but as the knife operates much more quickly, and with less violence to the parts, than scissars, which squeeze at the same time that they wound, it will be sparing the patient a great deal of pain to use the knife, wherever it is practicable; which it is in almost all cases, except some fistulas *in ano*, where the scissars are more convenient. The manner of opening with a knife, is by sliding it on a director, the groove of which prevents its being misguided. If the orifice of the abscess be so small as not to admit the director or the blade of the scissars, it must be enlarged by a piece of sponge-tent; which is made by dipping a dry bit of sponge in melted wax, and immediately squeezing as much out of it again as possible, between two pieces of tile or marble; the effect of which is, that the loose sponge being compressed into a small compass, if any of it be introduced into an abscess, the heat of the part melts down the remaining wax that holds it together, and the sponge sucking up the moisture of the abscess, expands, and in expanding opens the orifice wider, and by degrees, so as to give very little pain.

The usual method of dressing an abscess, the first time, is with dry lint only; or, if there be no flux of dressing of blood, with soft digestives spread on lint. If there be no danger of the upper part of the wound reuniting too soon, the dossils must be laid in loose. But if the abscess be deep, and the wound narrow, as is the case sometimes of abscesses *in ano*, the lint must be crammed in pretty tightly, that we may have afterwards the advantage of dressing down to the bottom without the use of tents, which, by resisting the growth of the little granulations of flesh, in process of time harden them, and in that manner produce a fistula: so that, instead of being used for the cure of an abscess, they never should be employed but where we mean to retard the healing of the external wound, except in some little narrow abscesses, where, if they be not crammed in too large, they become as dossils, admitting of incarnation at the bottom; but care should be taken not to inordinate them much deeper than the skin in this case, and that they be repeated twice a-day to give vent to the matter they confine. But tents do moist good in little deep abscesses, whence any extraneous body is to be evacuated, such as small splinters of bones, &c.

The use of vulnerary injections into abscesses has been thought to bear so near resemblance to the use of tents, that they both fell into disrepute almost at the same time.

Over the dossils of lint may be laid a large pledgit of tow spread with basilicon, which will lie softer than a defensive plaster; for this, though designed to defend the circumference of wounds against inflammation.

377

Of the
time, is with dry lint only; or, if there be no flux of dressing of blood, with soft digestives spread on lint. If there be no danger of the upper part of the wound reuniting too soon, the dossils must be laid in loose. But if the abscess be deep, and the wound narrow, as is the case sometimes of abscesses *in ano*, the lint must be crammed in pretty tightly, that we may have afterwards the advantage of dressing down to the bottom without the use of tents, which, by resisting the growth of the little granulations of flesh, in process of time harden them, and in that manner produce a fistula: so that, instead of being used for the cure of an abscess, they never should be employed but where we mean to retard the healing of the external wound, except in some little narrow abscesses, where, if they be not crammed in too large, they become as dossils, admitting of incarnation at the bottom; but care should be taken not to inordinate them much deeper than the skin in this case, and that they be repeated twice a-day to give vent to the matter they confine. But tents do moist good in little deep abscesses, whence any extraneous body is to be evacuated, such as small splinters of bones, &c.

tion or a fluxion of humours, is often the very cause of them: so that the dressings of large wounds should never be kept on by these plasters, where there is danger of such accidents. In this manner, the dressings may be continued till the cavity is incarned; and then it may be cicatrised with dry lint or some of the cicatrising ointments, observing to keep the fungus down, as directed before.

In the course of dressing, it will be proper to have regard to the situation of the abscess, and as much as possible to make the patient favour the discharge by his ordinary posture: and to this end also, the discharge must be assisted by compres and bandage: the compres may be made of rags or plaster; though the latter is sometimes preferable, as it remains immovable on the part it is applied to. The frequency of dressing will depend on the quantity of discharge: once in 24 hours is ordinarily sufficient; but sometimes twice, or perhaps three times, is necessary.

379 § 2. *Of making the Incision in cases of punctured Nerves and Tendons.*

As, in such cases, all the contiguous parts are supposed to be much swelled and in a state of high inflammation, it is impossible to get proper access either to the nerve or tendon, but by means of a large and extensive incision; and as this cannot be effected without some risk of opening at least some large branches of arteries, the first step to be taken in this operation is, to secure the parts against the effects of such an occurrence, by the application of the tourniquet on the superior part of the member. This precaution is necessary, not only for guarding against the loss of blood which would ensue from a division of any of the large arteries, but for preventing interruption during the operation, which would otherwise occur from a constant discharge of blood from the smaller vessels. The tourniquet indeed is more particularly requisite with a view to the prevention of this last inconvenience, than for any other reason; for although it is proper by means of it to guard against the effects to be expected from a division of any of the large arteries, yet, with proper caution, such an occurrence may in most cases be very easily avoided.

The tourniquet then being properly applied, a transverse incision should be made with a common scalpel upon the parts chiefly affected; and it ought to run in a direction exactly across the original orifice in the vein.

In no operation whatever is it more necessary than in this, to act with freedom in laying the parts sufficiently open by the external incision. A small incision puts the patient to nearly the same degree of pain as a larger cut; and it has this material inconvenience, that the surgeon cannot go on with the future steps of the operation with so much ease and expedition as when an extensive opening is made at first.

The external teguments being thus freely divided, the operator is now to proceed in a gradual manner, making one slight incision after another, taking care, if possible, to avoid wounding either the larger arteries or veins: and he is to go on in this way to endeavour to detect the wounded nerve; or if there is no possibility of doing so, even by great caution and nicety

in wiping away with a sponge every particle of blood as he goes along, he must still continue to proceed in this slow gradual manner, till he has divided every part between the skin and periosteum; the tendons, larger arteries and veins, excepted.

At this time the tourniquet should be loosened; and in all probability the patient will be found to express much satisfaction at what has been done: for if the part is thus divided which originally had been pricked by the lancet, and from whence all the subsequent distress proceeded, an immediate relief will now be obtained; but, on the contrary, if the pain still continues violent, we are thereby rendered almost certain of the mischief lying altogether in one or other of the tendons. An accurate examination, therefore, must now be made, by clearing the parts effectually with a sponge; and that tendon lying most contiguous to the vein in which the orifice was made, will in all probability be found either wounded, or in an evident state of inflammation: but at all events, whether any such appearance are detected or not, no hesitation whatever should occur as to the propriety of dividing that tendon which lies most contiguous to the vein; or if two or even three tendinous extremities should happen to lie in the way, and to be all therefore equally liable to suspicion, they ought all undoubtedly to be cut entirely across. This being properly effected, it will seldom occur that much relief is not immediately derived from it: and at any rate, this being done, every attempt will have been made from which we could expect any benefit to arise.

The parts having been thus freely divided, the tourniquet must now be made as slack as possible; and whatever arteries have been wounded, must be properly secured. The parts are then to be covered with soft easy dressings, and to be afterwards treated in the same manner as a wound from any other cause.

§ 3. *Of Issues and Setons.*

BOTH these are sometimes made by the knife; tho' the former are more frequently, and indeed more conveniently, put in by caustic. When incision is used, nothing more is necessary than with a lancet to make a small wound through the skin and cellular membranes. Into this is thrust a pea rubbed over with basilicon or some other ointment, which must be kept from slipping out of the wound by means of a proper bandage. By this extraneous body the wound is kept from healing, at the same time that, as the pea swells by the absorption of the juices of the body, the orifice is gradually enlarged, and the quantity of matter discharged from it is soon increased. This method, however, has an inconvenience, namely, that by thrusting the pea into a newly incised wound, the inflammation consequent upon even this small division of the solids is so great as to give a very considerable degree of pain.—The method of making issues by caustic is therefore preferred. The best caustic for this purpose is the *causticum commune* or *lapis infernalis* of the dispensatories, prepared from soap lees. A small bit of this is to be put upon the skin, the surrounding parts of which are to be defended from its action by a bit of adhesive plaster spread on leather. In a few hours a deep eschar is formed, part of which being im-

Practice. immediately cut out, and the opening filled with peafe, the rest soon separates, and is kept running with very little difficulty.

Setons are made in any part of the body by taking up the skin and subjacent cellular membrane between the fingers, then piercing through the fold with a lancet, and drawing through a soft cotton cord dipped in ointment. By this extraneous body the wound is kept in a constant state of suppuration, and the cord is every day drawn a little farther through, in order to discharge the matter, and prevent putrefaction.

SECT. III. Of Tooth-drawing.

TOOTH-drawing, according to Cicero, (*De Natura Deorum*, lib. 3. cap. 22.) was first invented by Æsculapius; in whose temple the ancients hung up a pair of leaden pincers, to signify that it would be dangerous and improper to extract any teeth but such as might be removed with leaden forceps, that is, such as are loose, and almost ready to fall out: for they do not consult their own welfare who imprudently remove their teeth, without absolute necessity, whilst they are sound and entire. For evulsion of the teeth is not only a dangerous and painful operation, but has even sometimes hazarded the patient's life: at least they impede the speech, and impair the act of mastication by this means; more especially in adults, in which we can have no hopes of others growing up in their room. However, it is sometimes absolutely necessary to draw teeth, 1. In infants, for removing those deciduous or lacteal teeth, which, being loosened by the fingers, may be extracted with a thread, or a pair of crow's-bill forceps; for when these teeth are left too long in the sockets, they may displace and turn the new ones awry. 2. It will be proper to extract those teeth in infants which grow out of the palate, or some other improper part of the mouth, which both hinder their speech and sucking. 3. Extraction is often the only method of relieving the toothach, which is very intense, proceeding from a caries in the teeth, and incapable of being eased by any medicines. 4. Those teeth ought to be drawn which, by their irregular figure and position, wound and lacerate the tongue, lips, and cheeks. 5. It is often absolutely necessary to draw a tooth for curing a fistula or ulceration of the gums next the teeth. The method of drawing them is as follows: If the tooth to be drawn is in the lower jaw, the patient must be seated on a low seat or on the floor; but when in the upper jaw, he must be seated on a high stool: after which, the surgeon takes his instrument best adapted to the case, and therewith draws out the tooth, as if extracting a nail out of a piece of wood, drawing the upper teeth downward, and the lower teeth upward; yet there is a particular sleight to be used, to avoid breaking the teeth. We shall conclude this section with observing, that though it is often absolutely necessary to remove or extract the teeth, yet you ought not to perform the operation while the patient's gums and parts adjacent remain inflamed and tumified.

SECT. IV. Of Ulcers.

WHEN a wound or abscess degenerates into so bad a state as to resist the method of cure described in treating of wounds, n° 64, &c. and loses that complexion which

VOL. X.

belongs to a healing wound, it is called an *ulcer*; and as the name is generally borrowed from the ill habit of the sore, it is a custom to apply it to all sores that have any degree of malignity, though they be immediately formed without any previous abscess or wound; such are the venereal ulcers of the tonsils, &c.

Ulcers are distinguished by their particular disorders, though it seldom happens that the affections are not complicated; and when we lay down rules for the management of one species of ulcer, it is generally requisite to apply them to almost all others. However, the characters of most eminence are, the callous ulcer, the sinuous ulcer, and the ulcer with caries of the adjacent bone: though there be abundance more known to surgeons, such as the putrid, the corrosive, the varicose, &c.; but as they have acquired their names from some particular affection, we shall speak of the treatment of them under the general head of ulcers.

It will be often in vain to pursue the best means of cure by topical application, unless we are assisted by internal remedies: for as many ulcers are the effects of a particular indispotion of body, it will be difficult to bring them into order, while the cause of them remains with any violence; though they are sometimes in a great degree the discharge of the indispotion itself, as in the plague, small-pox, &c. But we see it generally necessary in the pox, the scurvy, obstructions of the menes, dropsies, and many other distempers, to give internals of great efficacy; and indeed, there are hardly any constitutions where ulcers are not assisted by some physical regimen. Those that are cancerous and scrophulous seem to gain the least advantage from physic: for if in their beginnings they have sometimes been very much relieved, or cured, by salivation, or any other evacuation, they are also often irritated and made worse by them; so that there is nothing very certain in the effects of violent medicines in these distempers.

1. When an ulcer becomes foul, and discharges a nasty thin ichor, the edges of it, in process of time, tuck in, and, growing skinned and hard, give it the name of a *callous ulcer*; which, as long as the edges continue in that state, must necessarily be prevented from healing. But we are not immediately to destroy the lips of it, in expectation of a sudden cure; for while the malignity of the ulcer remains which was the occasion of the callosity, the new lips will be subject to a relapse of the same kind, however often the external surface of them be destroyed: so that, in this case, we are to endeavour to bring the body of the ulcer into a disposition to recover by other methods. It sometimes happens to poor laborious people, who have not been able to afford themselves rest, that lying a-bed will in a short time give a diversion to the humours of the part, and the callous edges, softening, will without any great assistance shoot out a cicatrix, when the ulcer is grown clean and filled with good flesh. The effect of a salivation is generally the same; and even an issue does not sometimes dispose a neighbouring ulcer to heal. But though callosities be frequently softened by these means, yet when the surface of the ulcer begins to yield thick matter, and little granulations of red flesh shoot up, it will be proper to quicken nature by destroying the edges of it, if they remain hard. The manner of doing this, is by touch-

ing them a few days with the lunar caustic, or *lapis infernalis*; and some choose to cut them off with a knife: but this last method is very painful, and not more efficacious; though, when the lips do not tuck down close to the ulcer, but hang loose over it, as in some venereal buboes, where the matter lies a great way under the edges of the skin, the easiest method is cutting them off with the scissars.

385
Of producing good matter.

To digest the ulcer, or to procure good matter from it when in a putrid state, there are an infinity of ointments invented; but the balsamico-inflavum alone, or softened down sometimes with turpentine, and sometimes mixed up with different proportions of red precipitate, seems to serve the purpose of bringing an ulcer on to cicatrization as well as any of the others. When the ulcer is incarnated, the cure may be finished as in other wounds; or if it do not cicatrize kindly, it may be washed with aq. calcis, or aq. phag. or dressed with a pledgit dipt. it tinct. myrrhae: and if excoriations are spread round the ulcer, they may be anointed with sperm. cet. ointment, or any other soft ointment.

The red precipitate has of late years acquired the credit it deserves for the cure of ulcers; but, by falling into general use, is very often unskillfully applied: when mixed with the balsicon, or, what is nearer, a cerate of wax and oil, it is most certainly a digestive, since it hardly ever fails to make the ulcer yield a thick matter in 24 hours, which discharged a thin one before the application of it.

386
Of destroying fungous flesh.

If the ulcer should be of such a nature as to produce a spongy flesh, sprouting very high above the surface, it will be necessary to destroy it by some of the escharotics, or the knife. This fungus differs very much from that belonging to healing wounds, being more eminent and lax, and generally in one mass; whereas the other is in little distinct protuberances. It approaches often towards a cancerous complexion, and when it rises upon some glands does actually degenerate sometimes into a cancer. When these excrescences have arisen in venereal ulcers, escharotics should be applied. Those in use, are the vitriol, the lunar caustic, the lapis infernalis, and more generally the red precipitate powder.

It is but seldom that these inveterate funguses appear on an ulcer; but it is very usual for those of a milder kind to rise, which may often be made to subside by pressure and the use of mild escharotics: however, if the aspect of the fore be white and smooth, as happens in ulcers accompanied with a dropsy, and often in young women with obstructions, it will answer no purpose to waste the excrescences until the constitution is repaired, when most probably they will sink without any assistance. In ulcers also, where the subjacent bone is carious, great quantities of loose flabby flesh will grow up above the level of the skin: but as the caries is the cause of the disorder, it will be in vain to expect a cure of the excrescence until the rotten part of the bone be removed; and every attempt with escharotics will be only a repetition of pain to the patient, without any advantage.

387
Of the posture of the body, &c.

When the pain and inflammation are excessive, bleeding and other evacuations will often be serviceable; and above all things, rest and a horizontal position; which last circumstance is of so great impor-

tance to the cure of ulcers of the legs, that unless the patient will conform to it strictly, the skill of the surgeon will often avail nothing: for as the indispotion of these sores is in some measure owing to the gravitation of the humours downwards, it will be much more beneficial to lie along than sit upright, though the leg be laid on a chair; since even in this posture they will defend with more force than if the body was reclined.

388
Of ulcers of the legs with varices.

1. In ulcers of the legs, accompanied with varices or dilations of the veins, the method of treatment will depend upon the other circumstances of the fore; for the varix can only be assisted by the application of bandage, which must be continued a considerable time after the cure. The neatest bandage is the laced stocking, which is particularly serviceable in this case; though also, if the legs be oedematous, or if, after the healing of the ulcers, they swell when the patient quits his bed, it may be worn with safety and advantage. There are instances of one vein only being varicous; which, when it happens, may be destroyed by tying it above and below the dilatation, as in an aneurism; but this operation should only be practised where the varix is large and painful.

Ulcers of many years standing are very difficult of cure; and in old people the cure is often dangerous, frequently exciting an asthma, a diarrhoea, or a fever, which destroys the patient, unless the fore break out again: so that it is not altogether advisable to attempt the absolute cure in such cases; but only the reduction of them into better order, and less compass, which, if they be not malignant, is generally done with rest and proper care. The cure of those in young people may be undertaken with more safety; and in all cases of stubborn ulcers, the bark, very copiously given, will be found of the utmost service.

389
Drying up of ulcers sometimes dangerous.

2. When an ulcer or abscess has any sinuses or channels opening and discharging themselves into the fore, they are called *sinuous ulcers*. These sinuses, if they continue to drain a great while, grow hard in the surface of their cavity; and then are termed *fistulae*, and the ulcer a *fistulous ulcer*; also, if matter be discharged from any cavity, as those of the joints, abdomen, &c. the opening is called a *sinuous ulcer* or a *fistula*.

390
Of sinuous ulcers.

The treatment of these ulcers depends upon a variety of circumstances. If the matter of the sinus be thick, strict bandage and compress will sometimes bring the opposite sides of the sinus to a reunion: if the sinus grow turgid in any part, and the skin thinner, showing a disposition to break, the matter must be made to push more against that part, by plugging it up with a tent; and then a counter opening must be made, which proves often sufficient for the whole abscess, if it be not afterwards too much tended, which locks up the matter and prevents the healing; or too little, which will have the same effect: for dressing quite superficially, does sometimes prove as mischievous as tents, and for nearly the same reason; since suffering the external wound to contract into a narrow orifice before the internal one be incarnated, does almost as effectually lock up the matter as a tent. To preserve, then, a medium in these cases, a hollow tent of lead or silver may be kept in the orifice, which, at the same time that it keeps it open, gives vent to the matter. The abscess where the counter opening is made

Practice. made most frequently, are those of compound fractures, and the breast: but the latter do oftener well without dilatation than the former; though it must be performed in both, if practicable, the whole length of the abscess, when after some trial the matter does not lessen in quantity, and the sides of it grow thinner; and if the sinuses be fistulous, there is no expectation of cure without dilatation. There are also a great many serophulous abscesses of the neck, that sometimes communicate by sinuses running under large indurations; in which instances, counter openings are advisable, and generally answer without the necessity of dilating the whole length; and indeed there are few abscesses in this distemper which should be opened beyond the thinness of the skin. When abscesses of the joints discharge themselves, there is no other method of treating the fistula, but by keeping it open, with the cautions already laid down, till the cartilages of the extremities of the bones being corroded, the two bones shoot into one another, and form an ankylosis of the joint, which is the most usual cure of ulcers in that part.

391
Of gunshot wounds, of serophulous abscesses in the neck.

392
Of gunshot wounds degenerating into sinuous ulcers. Gunshot wounds often become sinuous ulcers, and then are to be considered in the same light as those already described: though surgeons have been always inclined to conceive there is something more mysterious in these wounds than any others: but their terrible-ness is owing to the violent contusion and laceration of the parts, and often to the admission of extraneous bodies into them, as the bullet, splinters, bits of cloth, &c. and were any other force to do the same thing, the effect would be exactly the same as when done by firearms. The treatment of these wounds consists in removing the extraneous body as soon as possible; to which end the patient must be put into the same posture as when he received the wound: if it cannot be extracted by cutting upon it, which should always be practised when the situation of the blood-vessels, &c. does not forbid, it must be left to nature to work out, and the wound dressed superficially: for we must not expect that if it be kept open with tents, the bullet, &c. will return that way; and there is hardly any case where tents are more pernicious than here, because of the violent tension and disposition to gangrene which presently ensue. For dissolving of bullets, it has been recommended to inject mercury into the places where they are lodged; but this has never been known to answer any good purpose.

393
Of carious ulcers. 3. When an ulcer with loose rotten flesh discharges more than the size of it should yield, and the discharge is oily and stinking, in all probability the bone is carious; which may easily be distinguished by running the probe through the flesh: and if so, it is called a *carious ulcer*. The cure of these ulcers depends principally upon the removal of the rotten part of the bone, without which it will be impossible to heal; as we see sometimes even in little sores of the lower jaw, which taking their rise from a rotten tooth, will not admit of cure till the tooth be drawn. Those caries which happen from the matter of abscesses lying too long upon the bone, are most likely to recover: those of the pox very often do well, because that distemper fixes ordinarily upon the middle and outside of the densest bones, which admit of exfoliation; but those produced by the evil, where the whole extremities of

spongy parts of the bone are affected, are exceedingly dangerous: though all enlarged bones be not necessarily carious; and there are ulcers sometimes on the skin that covers them, which do not communicate with the bone, and consequently do well without exfoliation: nay, it sometimes happens, though the case be rare, that, in young subjects particularly, the bones will be carious to such a degree, as to admit a probe almost through the whole substance of them; and yet afterwards admit of a cure, without any notable exfoliation.

The method of treating an ulcer with caries, is by applying a caustic of the size of the scale of the bone that is to be exfoliated; and after having laid it bare, to wait till such time as the carious part can without violence be separated, and then heal the wound. In order to quicken the exfoliation, there have been several applications devised; but that which has been most used in all ages, is the actual cautery, with which surgeons burn the naked bone every day, or every other day, to dry up, as the say, the moisture, and by that means procure the separation; but as this practice is never of great service, and always cruel and painful, it is now pretty much exploded. Indeed, from considering the appearance of a wound, when a scale of bone is taken out of it, there is hardly any question to be made, but that burning retards rather than hastens the separation; for as every scale of a carious bone is slung off by new flesh generated between it and the sound bone, whatever would prevent the growth of these granulations would also in a degree prevent the exfoliation; which must certainly be the effect of a red-hot iron applied so close to it: though the circumstances of carious bones, and their disposition to separate, are so different from one another, that it is hardly to be gathered from experience, whether they will sooner exfoliate with or without the assistance of fire; for sometimes, in both methods, an exfoliation is not procured in a twelvemonth, and at other times it happens in three weeks or a month: however, if it be only uncertain whether the actual cautery be beneficial or not, the cruelty that attends the use of it should entirely banish it out of practice. It is often likewise, in these cases, employed to keep down the fungous lips that spread upon the bone: but it is much more painful than the escharotic medicines; though there will be no need of either, if a regular compress be kept on the dressings; or at worst, if a flat piece of the prepared sponge, of the size of the ulcer, be rolled on with a tight bandage, it will swell on every side, and dilate the ulcer without any pain.

Some caries of the bones are so very shallow, that they crumble insensibly away, and the wound fills and perfumes up; but when the bone will neither exfoliate nor admit of granulations, it will be proper to scrape it with a ruginé, or perforate it in many points with a convenient instrument down to the quick. In serophulous cases, the bones of the corpus and tarsus are often affected; but their sponginess is the reason that they are seldom cured: so that when these, or indeed the extremities of any of the bones, are carious through their substance, it is advisable to amputate; though there are instances in the evil, but more especially in critical abscesses, where, after long dressing down, the

Practice.

124
The actual cautery, as no reason in these ulcers.

395
Of scraping and perforating the bone, amputation, &c.

splinters, and sometimes the whole substance, of the small bones, have worked away, and, a healthy habit of body coming on, the ulcer has healed; but these are so rare, that no great dependence is to be laid on such an event. The dressings of carious bones, if they are stinking, may be doffed dipped in the tincture of myrrh; otherwise those of dry lint are easiest, and keep down the edges of the ulcer better than any other gentle applications.

396
Of burns.

Burns are generally esteemed a distinct kind of ulcers, and have been treated with a greater variety of applications than any other species of sore. When burns are very superficial, not raising suddenly any vesication, spirits of wine are said to be the quickest relief; but whether they be more serviceable than embrocations with linseed oil, is uncertain, though they are used very much by some persons whose trade subjects them often to this misfortune. If the burn excoerates, it is easiest to roll the part up gently with bandages dipped in sweet oil, or a mixture of unguent. flor. sambu. with the oil. When the excoriations are very tender, dropping warm milk upon them every dressing is very comfortable; or if the patient can bear to have flannels wrung out of it, applied hot, it may be still better. If the burn have formed eschars, they may be dressed with basilicon, though generally oil alone is easier; and, in these cases, whatever is the easiest medicine will be the best digestive. There is great care necessary to keep down the fungus of burns, and heal the wounds smooth: to which end, the edges should be dressed with lint dipped in aqua vitriol. and dried afterwards; or they may be touched with the vitriol stone, and the dressings be repeated twice a-day. There is also a greater danger of contractions from burns after the cure than from other wounds: to obviate which, embrocations of neats-foot oil, and bandage with pasteboards to keep the part extended, are absolutely necessary where they can be applied.

SECT. V. Of Sutures.

§ 1. The Interrupted Suture.

THE method of making the bloody-suture is as follows. The wound being emptied of the grumous blood, and your assistant having brought the lips of it together that they may lie quite even, you carefully carry your needle from without, inwards to the bottom, and so on from within, outwards; using the caution of making the puncture far enough from the edge of the wound, which will not only facilitate the passing the ligature, but will also prevent it from eating through the skin and flesh; this distance may be three or four tenths of an inch: as many more stitches as you shall make, will be only repetitions of the same process. The threads being all passed, you begin tying those in the middle of the wound; though, if the lips are held carefully together all the while, as they should be, it will be of no great consequence which is done first. The most useful kind of knot in large wounds is a single one first; over this a little linen compress, on which is to be made another single knot; and then a slip-knot, which may be loosened upon any inflammation: but in small wounds, there is no danger from the double knot alone, without any compress to tie it

upon; and this is most generally practised. If a violent inflammation should succeed, loosening the ligature only will not suffice; it must be cut through and drawn away, and the wound be treated afterwards without any suture. When the wound is small, the less it is disturbed by dressing the better; but in large ones, there will sometimes be a considerable discharge; and if the threads be not cautiously carried through the bottom of it, abscesses will frequently ensue from the matter being pent up underneath, and not finding issue. If no accident happen, you must, after the lips are firmly agglutinated, take away the ligatures, and dress the orifices which they leave.

It must be remembered, that during the cure the future must be always assisted by the application of bandage, if possible, which is frequently of the greatest importance; and that sort of bandage with two heads, and a slit in the middle, which is by much the best, will in most cases be found practicable.

§ 2. Suture of Tendons.

WOUNDS of the tendons are not only known to heal again, but even to admit of sewing up like those of the fleshy parts, though they do not reunite in so short a time.

As the wound of the skin will be nearly transverse, it should not be raised to expose more of the tendon, but rather sewed up with it, which will conduce to the strength of the suture. The knot of the ligature is to be made as in other wounds, and the dressings are to be the same: there is a sort of thin crooked needle that cuts on its concave and convex sides, which is very handy in the suture of large tendons, and to be preferred to the straight one. During the cure, the dressings must be superficial, and the parts kept steady with pasteboard and bandage: the small tendons reunite in three weeks, but the tendo Achillis requires six at least.

§ 3. Quilled Suture.

IN deep wounds, attended with much retraction, it is always a necessary precaution, to assist the operation of the ligatures by means of bandages, so applied as to afford as much support as possible to the divided parts: But, even with every assistance of this nature, it now and then happens, that the divided parts cannot be kept together, retraction occurs to a greater or lesser degree, and the ligatures of course cut afunder the soft parts they were at first made to surround.

With a view to prevent this receding of the teguments and other parts, it was long ago proposed to add to the interrupted suture what was supposed would afford an additional support, viz. quills, or pieces of plaster rolled up into the form of quills; one of which being placed on each side of the wound, the double of the ligature is made to include the one, and the knot to prels directly upon the other, instead of being made immediately on the edges of the sore, as was directed for interrupted sutures.

It is at once evident, however, that the ligatures must here make the same degree of pressure on the parts through which they pass as they do in the interrupted suture; and this being the case, it is equally obvious, that

Practice. that the interposition of these substances cannot be of any use. This future is accordingly now very rarely practised, and it is probable that it will be soon laid entirely aside.

§ 4. *The Glover's Suture.*

This future is termed the *glover's*, from being the one in common use among that set of people. As it is exceedingly simple, and very universally known, it does not here merit much description: we shall, therefore, just shortly observe, that it consists in a series of stitches all connected with one another, and continued in an oblique spiral direction along the course of the divided parts intended by it to be kept together.

This future has hitherto been universally employed for reuniting such parts of the intestines as have been divided by wounds: but, according to Mr Bell, the same end may be more perfectly attained, and probably with less danger, by means of the interrupted future; so that as this future has almost never been applied to any other purpose, it will likewise, in all probability, soon fall into disuse.

§ 5. *Twisted Suture.*

By the term *twisted future*, is meant that species of ligature by which parts, either naturally or artificially separated, are united together, by means of strong threads properly twisted round pins or needles pushed through the edges of the divided parts.

This future is commonly employed for the purpose of uniting the parts in cases of hare-lip; and this indeed is almost the only use to which it has been hitherto applied: But we may here remark, that it may with great advantage be put in practice in a variety of other cases; particularly in all artificial or accidental divisions either of the lips or cheeks; and in every wound in other parts that does not run deep, and in which futures are necessary, this future is preferable to the interrupted or any other.

In very deep wounds, for instance in all wounds extending to a greater depth than an inch and half, the interrupted future is the only one that is admissible; for in all such deep cuts, the pins necessary in the twisted future cannot with propriety be employed, as they cannot be introduced to such a depth, and afterwards so twisted with ligatures as to reunite the divided parts, but with great pain to the patient. In such wounds, therefore, we must of necessity have recourse to the interrupted future. But it may be here remarked, that wounds of this depth, requiring the aid of futures, are very rarely met with: so that, in by much the greatest proportion of wounds where futures are advisable, the twisted future will be found practicable; and whenever it is so, it ought certainly to be preferred to every other, as being obviously better calculated, even than the interrupted future, for the retention of divided parts. The pins made use of for twisting the threads upon ought to be made of a flat form, so as not to cut the parts through which they pass so readily as the ligatures employed in the interrupted future. And thus one great objection to the latter is very effectually obviated: for every practitioner must be sensible of this being the most faulty part of the interrupted future, that when muscular parts are divided so as to produce much retraction,

the ligatures employed for retaining them almost constantly cut them through before a reunion is accomplished; whereas the flatness of the pins used in the twisted future, and upon which, it may be remarked, the whole pressure produced by the ligatures is made to rest, proves in general a very effectual preventative against all such occurrences.

The pins used in this operation have commonly been made of silver; and in order to make them pass with greater ease, steel points have been added to them. As gold pins, however, are capable of receiving a sufficient degree of sharpness, which renders the intervention of steel points quite unnecessary; and as gold is fully more cleanly than silver, from its not acquiring so readily that kind of crust which immersion in fluids is apt to produce upon the other; pins of this metal are therefore preferable.

The manner of performing this operation is as follows. The divided parts intended to be reunited, must, by the hands of an assistant, be brought nearly into contact; leaving just as much space between the edges of the fore as to allow the surgeon to see that the pins are carried to a proper depth. This being done, one of the pins must be introduced through both sides of the wound, by entering it on one side externally, pushing it forwards and inwards to within a little of the bottom of the wound, and afterwards carrying it outwards through the opposite side, to the same distance from the edge of the fore that it was made to enter at on the other.

The distance at which the needle ought to enter from the edge of the fore, must be determined by the depth of the wound, and by the degree of retraction produced in the divided parts. In general, however, it is a proper regulation, in deep wounds, to carry the pins nearly to the same distance from the side of the fore as they are made to penetrate in depth: And it may be also remarked, that whatever the deepness of the wound may be, the pins ought to pass within a very little of its bottom; otherwise the parts which lie deep will run a risk of not being united, a circumstance which must always give rise to troublesome collections of matter.

In passing the pins through the different sides of the wound, if the skin and other teguments are not more firm than ordinary, it may commonly be done by the fingers alone, and particularly if the pins are made with small heads or knobs for the fingers to press upon; but when, from firmness of parts and other circumstances, much difficulty is expected to the entrance of the pins, the instrument termed *Porteguille* very effectually removes this inconvenience.

The first pin being passed in this manner very near to one end of the fore, and the parts being still supported by an assistant, the surgeon, by means of a firm waxed ligature, passed three or four times round and across the pin, so as nearly to describe the figure of 8, is to draw the parts through which it has passed into immediate and close contact: and the thread being now secured with a loose knot, another pin must be introduced in the same manner at a proper distance from the former; and the thread with which the other was fixed being loosed, and in the same manner carried round this pin, others must be introduced at proper distances along the whole course of the wound

Practice.

⁴⁰² Gold pins recommended for this future.

⁴⁰³ Manner of performing the operation.

⁴⁰¹ The twisted future may be used in a variety of other cases besides the hare-lip.

and the same ligature ought to be of a sufficient length for securing the whole.

The number of pins to be used must be determined entirely by the extent of the wound. Whenever this future, however, is practised, whether the wound be large or of very small extent, a pin ought to be introduced very near to each end of it, otherwise the extremities of the fore are apt to separate so as not to be afterwards easily reunited. In large wounds, if the pins are introduced at the distance of three quarters of an inch from one another, it will in general be found sufficient; but in cuts of smaller extent, a greater number of pins become necessary in proportion to the dimensions of the fores.

Thus in a wound of an inch and half in length, three pins are absolutely requisite; one near to each end, and another in the middle of the fore: whereas five pins will always be found fully sufficient for a wound of three inches and a half in extent, allowing one to be within a quarter of an inch of each extremity of the wound, and the others to be placed along the course of the fore at the distance of three quarters of an inch from one another.

The pins being all introduced and secured in the manner directed, nothing remains to be done, but to apply a piece of lint wet with mucilage all along the course of the wound, with a view to exclude, as effectually as possible, every access to the external air.

In order to prevent the ends of the pins from pressing upon and hurting the skin below, it is usual to apply a small bolster of linen or charpie under each of them; but as this always does mischief, by tending to press upon the pins, so as to force them to act upon the soft parts through which they have passed, every thing of this kind ought to be omitted. When, however, the patient happens to complain of being hurt by the ends of the pins, this may be easily prevented, by introducing between them and the skin pieces of thin linen spread with any adhesive plaster.

In order to give every chance of success to this operation, it has been commonly advised, immediately after the pins are secured, to apply the uniting bandage over the whole, so as to afford as much support as possible to the contiguous parts. The least reflection, however, renders it evident, that every degree of pressure made in this manner must do mischief; for the bandage being made to rest immediately upon the pins, a considerable degree of pain and consequent inflammation must of course be produced by it: And in fact this is so much the case, that in every instance in which we have seen this bandage applied, it either did harm, by exciting inflammation in consequence of too much pressure upon the pins; or, if that effect was not produced, no advantage was received from it, from the bandage not being applied with such tightness as to afford any support whatever to the parts below.

The next point to be determined, is the time the pins should be allowed to remain. When they remain long, they generally do harm, by the unnecessary irritation and consequent retraction of parts with which they are always attended; and again, if they are not continued for a sufficient length of time, that degree of adhesion is not produced between the divided parts that is necessary for their future retention; so that the

effect of the operation comes to be in a great measure, if not entirely, lost.

In wounds of no great depth, for instance of three quarters of an inch or so, a sufficient degree of adhesion always takes place in the space of five days; and six, or at most seven days, will generally be found sufficient for wounds of the greatest depth. But with respect to this circumstance, it must always be understood, that the patient's state of health must have a considerable influence on the time necessary for producing adhesion between divided parts. In specifying the time necessary for this purpose, the operation is supposed to have been done on a constitution in a state of perfect health. When the patient labours under scurvy, or any disorder which affects the general system, it is impossible to ascertain this circumstance with precision: in such cases we must be determined by the nature and state of the disease present at the time.

So soon as the pins are withdrawn, the uniting bandage may be then applied with great advantage, in order to serve as a support to the parts newly united; but as slips of leather spread with ordinary glue, when applied to each side of the cicatrix, may, by means of ligatures properly connected with them, be made to answer this purpose in a more effectual manner, this mode of supporting the parts ought of course to be preferred.

SECT. VI. Of the Ligature of Arteries.

A surgeon being called to a person losing much blood from the division of any of the larger vessels, the first step to be taken is, by means of strong compression, to effect a temporary stoppage of the discharge, till, by the application of ligatures, a more effectual remedy is obtained.

When accidents of this nature occur in any of the extremities, and where pressure can be made with ease on the superior parts of arteries, for such cases we are in possession of a remedy, which, when skilfully applied, never fails of producing an immediate stop to all farther loss of blood. What is here meant is the tourniquet.

Till the invention of this instrument, no operation of importance could be undertaken on any of the extremities but with great hazard to the patient; and large wounds must have frequently proved mortal from the want of this assistance, which otherwise might not have been in any degree hazardous.

As the invention of the tourniquet is claimed by different people, and even by different nations, we shall not here pretend to say from whence it originally came: but whoever had the merit of it, the first instrument of this kind with which the world was made acquainted was exceedingly simple; so much indeed, that we now reflect with astonishment at the discovery having been reserved to such a very late period. A small cushion being placed upon the course of the principal artery of a limb, a circular rope or bandage was made to pass twice round it; and a small wooden handle being then introduced between one of the folds of the bandage, for the purpose of twisting it, the cushion by these means was pressed with so much force upon the artery, as to put an effectual stop to the course of the blood through the under part of the limb.

Improvements by
Mr Pott.

Mr Petit, an eminent surgeon of Paris, was the first who proposed a considerable improvement on this instrument, by connecting the circular bandage with a screw, which was so contrived as to produce the pressure chiefly on the principal arteries, without materially affecting the rest of the limb. It had this advantage over the other instrument, that the operator himself could manage it, without being under the necessity of employing an assistant: but it was liable to one great inconvenience, from the very circumstance which by the inventor was considered as an improvement. This instrument of Mr Petit being made to act upon the principal arteries only, the smaller vessels communicating with these, by not being properly compressed, discharge blood freely from the infant they are cut; and as this proves a very troublesome circumstance in the course of operations, different improvements have of late been made upon it.

By means of this instrument in its now improved state, the blood in any limb is very easily and effectually commanded; and as it grasps the whole member equally, all the collateral branches, as well as the principal arteries, are equally compressed by it. It has this material advantage, too, over every other instrument of this kind, that, when properly applied, a single turn, or even half a turn, of the screw, is sufficient for producing either a flow of blood, or for putting a total stop to it. The manner of using it is as follows.

410
Manner of
using it.

Let a cushion of three inches in length by one inch and half in diameter, be prepared of a linen roller, and be made tolerably firm, but yet not so hard as to render pressure produced by it very painful. This being placed upon the course of the principal artery of the limb, is to be firmly secured in that situation by one or two turns of a circular roller, of the same breadth with the cushion itself.

The instrument, with the strap connected with it, being now placed upon the limb, with the handle of the screw on the opposite side of the member to the cushion upon the artery, the strap is to be carried round the limb directly over the cushion, and to be firmly connected on the other side to the buckle. In thus connecting the strap and buckle together, particular attention is necessary in doing it with great firmness, so as that the screw may afterwards operate with as much advantage as possible in producing a sufficient degree of pressure. When proper attention is paid to this circumstance, a single turn of the screw proves sufficient for putting an entire stop to the circulation of blood in the limb: but when the strap has not originally been made very tight, several turns of the screw become necessary; an occurrence which may be always very easily prevented, and which, when not attended to, frequently proves very embarrassing in the course of an operation.

411
Of securing
arteries by
means of
the curved
needle.

Various methods have been invented for securing arteries by means of ligatures. The practice lately in ordinary use was, by means of a curved needle, to pass a ligature of sufficient strength round the mouth of the bleeding vessel, including a quarter of an inch all round of the surrounding parts, and afterwards to form a knot of a proper tightness upon the vessel and other parts comprehended in the noose. But this method has been found to give so much pain, that the

best practitioners have thought proper to reject it, and to tie up the blood-vessels by themselves.

In order to detect the arteries to be tied, the tourniquet, with which they are secured, must be slackened a little by a turn or two of the screw; and the moment the largest artery of the fore is discovered, the surgeon fixes his eye upon it, and immediately restrains the blood again by means of the tourniquet. An assistant now forms a noose on the ligature to be made use of; and this noose being placed immediately over the end of the artery, so as to include it with certainty, the operator then pushes the sharp point of the tenaculum through the sides of the vessel, and at the same time pulls so much of it out, over the surface of the surrounding parts, as he thinks is sufficient to be included in the knot which the assistant is now to make. In forming this ligature, the surgeon's knot, as it is termed, which consists in passing the thread twice through the first noose, is certainly preferable to every other, from its being less liable to yield or slip. And as some additional security is obtained by forming a second knot above the first, this precaution ought never to be omitted. It is easily done; and on security in this point the patient's life may in a great measure depend.

The degree of strength of the ligature must always be proportioned to the size of the vessels; but this is a circumstance to be at all times determined by the judgment of the practitioner, as must also the force to be employed in forming the knots. To what was already said upon this point, we shall just add, that a very small force is fully sufficient for securing even the largest arteries; and that after such a force has been applied as evidently restrains the farther loss of blood, a very trifling additional compression is all that is in any degree necessary.

The operator ought to be provided with needles of various sizes, and of different forms. The needles in ordinary use are, for many purposes, quite too much crooked; for, in general, they are more easily managed when their curvatures are not so considerable.

The same kinds of needles as are found necessary for the interrupted suture, answer equally well for the ligature of arteries.

The needles in common use are made triangular, with three different edges, one on each side, and a third on the concave part of the needle. There is no real necessity, however, for more than two; indeed the needle enters fully more easily with two than with three edges; and as the third edge on the concave side renders them more liable to injure arteries and other parts in the course of their introduction, this addition ought therefore to be omitted.

A needle of this shape, armed with a ligature of size proportioned to itself and to the vessel to be taken up, is to be introduced at the distance of a sixth or eighth part of an inch from the artery, and pushed to a depth sufficient for retaining it, at the same time that it is carried fully one-half round the blood-vessel. It must now be drawn out; and being again pushed forward till it has completely encircled the mouth of the artery, it is then to be pulled out, and a knot to be tied of a sufficient firmness, as was already directed when the tenaculum is used.

SECT. VII. *Of the Treatment of Aneurisms.*

In every case of aneurism, the use of pressure has been indiscriminately recommended, not only in the incipient period of the disease, but even in its more advanced stages.

414
Of the effects of pressure in aneurisms.

In the diffused or false aneurism, pressure has been universally advised, not only with a view to dissipate the swelling already induced, but in order to produce a reunion of the wound in the artery; however, as pressure in such cases cannot be applied to the artery alone, without at the same time affecting the refluxent veins; and as this circumstance, by producing an increased resistance to the arterial pulsations, must undoubtedly force an additional quantity of blood to the orifice in the artery; therefore no advantage is to be expected from it; but on the contrary, there is reason to suppose it has been on many occasions productive of mischief.

But although pressure ought never to be attempted in any period of the diffused aneurism, yet in some stages of the other species of the disease, it may be often had recourse to with advantage.

In the early stages of encysted aneurism, while the blood can be yet pressed entirely out of the sac into the artery, it often happens, by the use of a bandage of soft and somewhat elastic materials, properly fitted to the part, that much may be done in preventing the swelling from receiving any degree of increase; and on some occasions, by the continued support thus given to the weakened artery, complete cures have been at last obtained. In all such cases, therefore, particularly in every instance of the varicose aneurism, much advantage may be expected from moderate pressure.

But although pressure to a certain degree has frequently, in cases of encysted aneurism, proved very useful, it ought never to be carried to any great length; for tight bandages in all such affections, by producing an immoderate degree of reaction in the containing parts to which they are applied, instead of answering the purpose for which they were intended, have evidently the contrary effect. Moderate compression, therefore, is more eligible than a great degree of it; and indeed the greatest length to which pressure in such cases ought to go, should be to serve as an easy support to the parts affected, and no farther.

415
Of performing the operation for an aneurism.

The first step in this operation ought to be to obtain a full command of the circulation in the inferior part of the member by means of the tourniquet applied above. This being done, the patient should be so placed, that the diseased limb, on being stretched on a table, is found to be of a proper height for the surgeon; who, as the operation is generally tedious, ought to be seated. The limb being in this situation properly secured by an assistant, the operator is now with a scalpel to make an incision through the skin and cellular substance along the whole course of the tumour; and as freedom in the remaining parts of the operation is here a matter of much importance, it is even of use to carry this external incision half an inch or so both above and below the farthest extremities of the swelling.

This being done, the ordinary method is to proceed

in a very slow cautious manner, dissecting away one layer of the membrane after another, till the artery itself is laid bare. In this manner the operation is always rendered exceedingly tedious, as the thickness of parts with which the artery is found covered, is often really astonishing, by one layer of a membranous substance having been formed after another, from the coagulable lymph of the blood contained in the tumour. In reality, however, there is no necessity for this degree of caution, as the operation may, in the following manner, be equally well performed in a much shorter space of time, and with much less pain to the patient.

So soon as the external incision has been made in the manner directed, so as to divide the skin and cellular substance, all the effused blood ought to be wiped off by means of a sponge; and the softest part of the tumour being discovered, an opening ought there to be made into it with a lancet, large enough for admitting a finger of the operator's left hand. This being done, and the finger introduced into the cavity of the tumour, it is now to be laid open from one extremity to the other, by running a blunt-pointed bistoury along the finger from below upwards, and afterwards from above downwards, so as to lay the whole cavity fairly open.

The cavity of the tumour being thus laid freely open, all the coagulated blood is now to be taken out. For this purpose a number of instruments, particularly scoops, have been invented by different operators; but no instrument answers this intention so effectually, and with so much ease to the patient, as the fingers of the operator; who having in this manner removed all the coagulated blood, together with a number of tough membranous filaments commonly found here, the cavity of the tumour is now to be rendered quite dry, and free from the blood which, on the first opening of the swelling, is discharged into it from the veins in the inferior part of the member; and this being effectually accomplished, the tourniquet must be made perfectly slack and easy, in order to discover, not only the artery itself, but the opening into it, from whence the blood collected in the tumour has been all along discharged. This being done, the next point to be determined, is the manner of securing this opening into the artery, so as to prevent in future any farther effusion of blood. Various means have been proposed for accomplishing this; but the effects of all of them may be comprehended under the three following heads.

I. The effects of ligature upon a large artery have on some occasions proved fatal to the inferior part of the member, it was long ago proposed, that so soon as the opening into the artery has been discovered, instead of applying a ligature round it, which for certain is to obliterate its cavity entirely, a piece of agaric, vitriol, alum, or any other astringent substance, should be applied to the orifice, in order, if possible, to produce a reunion of its sides.

II. Upon the same principle with the preceding, Mr. Lam-
viz. that of still preserving the circulation in the artery, it was several years ago proposed by an eminent surgeon of Newcastle, Mr. Lambert, that the orifice in the artery should be secured by means of the twisted suture. A small needle being pushed through the
edges

416
Means of preventing an hæmorrhage.

417
Mr. Lambert's proposal of stitching the wound in the artery

Practice.

edges of the wound, they are then directed to be drawn together by a thread properly twisted round the needle, as was formerly directed when treating of fistules.

Strong objections, however, occur to both of these methods. In the first place, no astringent application with which we are acquainted is possessed of such powers as to deserve much confidence; for although different articles of this kind have on various occasions proved a means of putting a temporary stop to hæmorrhages, yet there are very few instances properly authenticated of their having produced any permanent advantage. In almost every instance in which they have been used, the hæmorrhage has recurred again and again, so as to prove very distressing, not only to the patient, but to the practitioner in attendance; so that, from this want of success, little or no attention is now paid to remedies of this kind in ordinary practice.

418
Objections
to Mr Lam-
bert's me-
thod.

With regard to Mr Lambert's method of stitching the orifice in the artery, it is certainly a very ingenious proposal; and would in all probability, at least in most instances, prove an effectual stop to all farther discharge of blood: but as we have yet only one instance of its success, little can yet be said about it. Two material objections, however, seem to occur to this practice. One is, that in the operation for the aneurism, in almost every instance, a very few only excepted, the artery lies at the back-part of the tumour; so that when all the collected blood is removed, there is such a depth of wound, that it must be always a very difficult matter, and on many occasions quite impracticable, to perform this nice operation upon the artery with that attention and exactness which, in order to ensure success, it certainly requires. It has now and then happened, indeed, that in this operation the artery has been found to be on the anterior part of the tumour; and in such a situation the wound in it would no doubt prove accessible enough. This, however, is a very rare occurrence, as in almost every instance of diffused aneurism, the artery lies at the very bottom of the tumour, by the blood being collected between it and the common teguments; and accordingly, in several instances of this disorder, in which, after the tumour was laid freely open, the artery has been found to lie so deep, as would have rendered it quite impossible to perform this operation.

But there is another very material objection which *à priori* evidently occurs to the practice recommended by Mr Lambert. By introducing a needle through the sides of the orifice, and drawing these together by a ligature, the cavity of the artery must undoubtedly be at that point much diminished. Indeed Mr Lambert, in his account of the case in which this operation was performed, acknowledges that the diameter of the artery was thereby diminished. Now the passage of the blood being thus contracted at one point, the impulse upon that particular part must be very considerable: So that the very remedy employed for the cure of one species of aneurism, will in all probability prove a very powerful agent in inducing another; for the blood being thus obstructed in its usual course, there will be no small danger incurred of a dilatation being produced immediately above this preternatural stricture.

VOL. X.

III. Neither of the methods we have yet been considering being found eligible for securing the orifice in the artery, we shall now proceed to describe the ordinary manner of performing this operation; which consists in obliterating the arterial cavity entirely by means of ligatures.

The artery being laid bare in the manner directed, and all the coagulated blood being carefully removed from the cavity of the tumour, on the tourniquet being now slackened so as to bring the orifice in the artery into view, a small probe is to be introduced at the opening, in order to raise the artery from the neighbouring parts, so as that the surgeon may be enabled with certainty to pass a ligature round it, without comprehending the contiguous nerves, which in general run very near to the large blood-vessels of a limb. By this precaution the nerves may be always avoided; and by doing so, a great deal of mischief might be prevented, which otherwise in all probability might supervene. When the disorder is situated either in the arm, or in the usual part of blood-letting in the arm, bending the joints of the knee or of the elbow, as it relaxes the artery a little, renders this part of the operation more easily effected than when the limbs are kept fully stretched out.

The artery being thus gently separated from the contiguous parts, a firm, broad, waxed ligature must be passed round it, about the eighth part of an inch or so above the orifice, and another must in the same manner be introduced at the same distance below it. Much harm, in all probability, has been done by passing the ligature so far distant from the orifice as is commonly practised; for the risk of losing the benefit of anastomosing branches will be always increased in proportion to the extent of artery included between the ligatures.

The easiest method of introducing the ligatures is by means of a blunt-curved needle. An ordinary sharp needle is commonly made use of for this purpose; but it does not answer the intention so well as the one here recommended: by the sharpness of its points it is apt to injure the contiguous parts; and when the common crooked needle is used with a sharp edge on its concave side, there must even be some risk of its wounding the under part of the artery, as in this situation it cannot be introduced without making this part of the needle pass quite in contact with the coats of the artery. The blunt needle is not liable to either of these objections; and besides is more easily introduced than any of the ordinary aneurismal needles.

The ligatures being both passed in the manner directed, the upper one is now to be tied with a firm-⁴¹⁹ness sufficient for compressing the sides of the artery, the ligature. The directions formerly given for forming the knot upon bleeding-vessels in other parts, will apply with equal propriety here: the ends of the ligature ought by all means to be twice passed through the first noose, and this should again be farther secured by a single knot made above it. By many writers on this subject, a small bolster of linen is ordered to be inserted between the artery and the knot, in order to prevent the artery from being cut by it. This, however, is a very unnecessary precaution; for if the whole artery is not surrounded with the bolster, it will be just as

42 E

much

Practice.

much exposed to be cut by the ligature at any other part as where the knot is fixed: and, besides, as we have already remarked, there is no occasion whatever for making the ligature so tight on arteries as to run any risk of dividing them; a much less degree of pressure than is either commonly applied, or than could have any influence in hurting them, being fully sufficient for compressing them in the most effectual manner.

The upper ligature being thus finished, before the knot is passed upon the other below the orifice, the tourniquet ought to be untwisted, in order to see whether any blood is now discharged by the wound in the artery or not. If blood flows in any considerable quantity, it affords a prospect of success, as it clearly shows, that the anastomosing branches from the superior part of the artery are considerable enough for carrying on at least a tolerable degree of circulation in the under part of the member. At the same time, however, although blood should not be discharged at this time by the orifice, we are by no means, from this circumstance alone, to despair of success; for it frequently happens, that the operation succeeds in a very effectual manner, although no blood whatever is discharged on the trial now recommended.

But whether any blood should be discharged by this trial or not, we are not to rest satisfied with one ligature; for unless the ligature below the orifice be also tied, there is always a risk, on the return of circulation to the under part of the artery, of blood passing out at the orifice. This precaution, therefore, should never be omitted; it is easily done, and it renders the patient quite secure against all farther evacuation of blood by the orifice. After the knots have been put upon the ligatures, these should be cut of such a length, that their ends may lie fully out over the edges of the wound; so that when necessary they may be more easily withdrawn.

By way of greater security in this operation, it has been advised to insert other two ligatures quite contiguous to the former, and to leave them untied; so that if any of the others misgive, its place may be immediately supplied.

There is not, however, any necessity for this precaution: for if the first ligatures are properly applied, there can be no doubt of their answering the purpose; and in case either one or both of them should happen to fail, they can be very easily renewed. In the mean time, too, the patient is rendered safe against any sudden loss of blood, by the tourniquet being left loose upon the upper part of the member; which it ought by all means to be for several days after the operation, so that, in the event of blood bursting from the wound, it may be secured by means of it, much more readily than if it depended on the tying of a ligature.

The ligatures being both finished in the manner directed, the tourniquet is now to be made quite loose; and if no blood is discharged at the orifice in the artery, we may then rest satisfied that the operation is so far properly completed.

The wound is now to be lightly covered with soft lint, with a pledget of any emollient ointment over the whole; and a compress of linen being applied over the dressings, all the bandage in any degree requisite, is, two or three turns of a roller above, and as many be-

low the centre of the wound, making it press with no more tightness than is absolutely necessary for retaining the applications we have just now mentioned.

The patient being now put into bed, the member should be laid in a relaxed posture upon a pillow, and ought to be so placed as to create the least possible uneasiness from the posture in which it is laid.

As the operation for the aneurism is always tedious, and produces much pain and irritation, a full dose of laudanum should be given immediately on the patient being got into bed. In order to diminish sensibility, during some of the more capital operations, different trials have been made of opiates given an hour or so before the operation. On some occasions, this proved evidently very useful; but in others it seemed to have the contrary effect; particularly in weak nervous constitutions, in which with any dose, however small, they appeared to be rendered more irritable and more susceptible of pain, than if no opiate had been given. Immediately after this operation, however, an opiate ought to be exhibited, to be repeated occasionally according to the degrees of pain and restlessness.

In some few cases of aneurism it has happened, that the pulse in the under part of the member has been discovered immediately after the operation. This, however, is a very rare occurrence: For as this disorder is seldom met with in any other part than at the joint between the elbow as a consequence of blood-letting, and as it rarely happens that the brachial artery divides till it passes an inch or two below that place, the trunk of this artery is therefore most frequently wounded; and when, accordingly, the ligature in this operation is made to obliterate the passage of almost the whole blood that went to the under part of the arm, there cannot be the least reason to expect any pulsation at the wrist, till in a gradual manner the anastomosing branches of the artery have become so much enlarged, as to transmit such a quantity of blood to the inferior part of the member as is sufficient for acting as a stimulus to the larger branches of the artery.

Immediately after the operation, the patient complains of an unusual numbness or want of feeling in the whole member; and as it generally for a few hours becomes cold, it is therefore right to keep it properly covered with warm soft flannel; and in order to serve as a gentle stimulus to the parts below, moderate frictions appear to be of use. In the space of ten or twelve hours from the operation, although the numbness still continues, the heat of the parts generally begins to return; and it frequently happens, in the course of a few hours more, that all the inferior part of the member becomes even preternaturally warm.

Immediately after this operation, the want of feeling in the parts is often very great; and in proportion as the circulation in the under part of the member becomes more considerable, the degree of feeling also augments. If we could suppose the nerves of the parts below to be always included in the ligature with the artery, that numbness which succeeds immediately to the operation might be easily accounted for; but it has been also known to happen when nothing but the artery was secured by the ligature.

421
Of dressing
the wound.

Practice.

In the mean time the patient being properly attended to as to regimen, by giving him cordials and nourishing diet when low and reduced, and confining him to a low diet if his constitution is plethoric, the limb being still kept in an easy relaxed posture, towards the end of the fourth or fifth day, sometimes much sooner, a very weak feeble pulse is discovered in the under part of the member, which becoming stronger in a gradual manner, the patient in the same proportion recovers the use and feeling of the parts.

414
Of taking away the ligatures.

So soon as there is an appearance of matter having formed freely about the fore, which will seldom happen before the fifth or sixth day, an emollient poultice should be applied over it for a few hours, in order to soften the dressings, which may be then removed. At this time, too, the ligatures might be taken away; but as their continuance for a day or two longer can do no harm, it is better to allow them to remain till the second or third dressing, when they either drop off themselves, or may be taken away with perfect safety. The dressings, which should always be of the softest materials, being renewed every second or third day according to the quantity of matter produced, the fore is in general found to heal very easily; and although the patient may for a considerable time complain of great numbness and want of strength in the whole course of the diseased limb, yet in most instances a very free use of it is at last obtained.

415
In what cases a mortification will happen.

It will be readily supposed, that the termination of this operation, as we have here described it, is the most favourable that can possibly happen. In some instances, the success attending it is far from being so complete: Instead of a return of circulation, and of the feeling and use of the parts, they remain cold and insensible, and no marks of returning life are perceived. From a mere want of blood, therefore, mortification at last commences; and as nature is here deprived of one of her principal agents for the removal or separation of gangrenous parts, viz. the efforts of the sanguiferous system, whenever the parts in such circumstances begin to mortify, nothing can prevent their progress to the ultimate stage of that malady.

Whenever mortification ensues, therefore, as a consequence of this operation, if the patient survives the immediate effects of it till a separation occurs between the healthy and diseased parts, amputation of the member will then be the only resource.

SECT. VIII. Of Fractures and Dislocations.

416
Of the bandages most proper for fractures.

The best and most useful bandage for a simple fracture of the leg or thigh, is what is commonly known by the name of the *eighteen-tailed bandage*; or rather one made on the same principle, but with a little difference in the disposition of the pieces. The common method is to make it so, that the parts which are to surround the limb make a right angle with that which runs lengthwise under it; instead of which, if they are tacked on so as to make an acute angle, they will fold over each other in an oblique direction, and thereby fit more neatly and more securely, as the parts will thereby have more connection with, and more dependence on, each other.

The parts of the general apparatus for a simple

fracture, which come next in order, are the splints. Practice.

These are generally made of pasteboard, wood, or some resisting kind of stuff, and are ordered to be applied lengthwise on the broken limb; in some cases three, in others four, for the more steady and quiet detention of the fracture. That splints properly made and judiciously applied are very serviceable, is beyond all doubt; but their utility depends much on their size, and the manner in which they are applied. In general practice, they are made of such length as not to reach either upward or downward, so far as the roller extends; nor to comprehend either the upper or the lower joint of the broken bone, and to exceed the fracture either way not many inches: They do not, for example, in the broken leg, comprehend either the joint of the knee or the joint of the ankle, and act only on the fracture.

In this manner of application, and of this size, they are in fact neither more nor less than compresses, and compresses made of very bad materials. All the good that ever is, or that can be, done by them, when of such length, and so applied, might certainly be done in a better manner by a more proper kind of compress; and every disadvantage which a hard resisting compress, injudiciously applied, is capable of producing, is probable to result from them thus used.

The true and proper use of splints is to preserve steadiness in the whole limb, without compressing the fracture at all. By the former, they become very assistant to the curative intention; by the latter, they are very capable of causing pain and other inconveniences; at the same time that they cannot, in the nature of things, contribute to the steadiness of the limb.

In order to be of any real use at all, splints should, in the case of a broken leg, reach above the knee and below the ankle; should be only two in number; and should be so guarded with tow, rag, or cotton, that they should press only on the joints, and not at all on the fracture. By this they become really serviceable; but a short splint, which extends only a little above and a little below the fracture, and does not take in the two joints, is an absurdity. By pressing on both joints, they keep not only them but the foot steady; by pressing on the fracture only, they cannot retain it in its place, if the foot be in the smallest degree displaced; but they may, and frequently do, occasion mischief, by rudely pressing the parts covering the fracture against the edges and inequalities of it.

In the case of a fractured os femoris, if the limb be laid in an extended posture, one splint should certainly reach from the hip to the outer ankle, and another (somewhat shorter) should extend from the groin to the inner ankle. In the case of a broken tibia and fibula, there never can be occasion for more than two splints; one of which should extend from above the knee to below the ankle on one side, and the other splint should do the same on the other side.

The most essential article in the treatment of a fracture is the position of the limb. Upon the judiciousness of the or injudicious execution of this, depends the ease of limbs.

the patient during his confinement, and the free use and natural appearance of his limb afterward.

“If I meant to describe (says Mr Pott), or if I approved (pardon the phrase), the common method of

42 E 2 placing

Practice.

placing the broken leg and thigh in a straight manner, this would be the place to mention the many very ingenious contrivances and pieces of machinery which practitioners, both ancient and modern, have invented for the purpose of keeping the whole limb straight and steady; that is, of keeping all the muscles surrounding the fractured bone constantly upon the stretch, and at the same time of preventing any inequality in the union of it, and any shortening of the limb in consequence of such inequality. But as it is my intention to inculcate another, and as it appears to me a better disposition of the limb, in which such boxes, cradles, and pieces of machinery are not wanted, nor can be used, it is needless for me to say any thing about them.

"According to this plan, the fractured leg and thigh should be deposited on the pillow in the very posture in which the extension was made and the fracture set; that is, with the knee bent.

"In the case of the fractured os humeri, the only position in which it can, with any tolerable convenience to the patient, be placed, is with the elbow bent; that very position which necessarily relaxes and removes all the resistance of the surrounding muscles. Daily experiences evince the utility of this, by our very seldom meeting with lameness or deformity after it, notwithstanding the prevailing apprehension of exuberant callus.

"The deformity frequently consequent to the fracture of the bones of the cubit, particularly that of the radius only, will generally, if not always, be found to be in proportion as the muscles concerned in the pronation and supination of the hand happen to be put more or less into a state of action or tension by the position of the limb.

"In the thigh the case is still more obvious, as the muscles are more numerous and stronger. The straight posture puts the majority of them into action: by which action, that part of the broken bone which is next to the knee is pulled upward, and by passing more or less underneath that part which is next to the hip, makes an inequality or rising in the broken part, and produces a shortness of the limb.

"In the fracture of both bones of the leg, the case is still the same: a straight position puts the muscles upon endeavouring to act; a moderate flexion of the knee relaxes them, and takes off such propensity.

429
Of the fractured cubit.

"The disposition, therefore, of the broken cubit ought to be that which, by putting the hand into a middle state between pronation and supination, and by bending the fingers moderately, keeps the radius superior to the ulna; or, in other words, the palm of the hand should be applied to the breast, the thumb should be superior, the little finger inferior; and the hand should be kept in this posture constantly by means of two splints, which should reach from the joint of the elbow on each side, and should be extended below the fingers: or the same purpose may be still better answered by a simple neat contrivance of the very ingenious Mr Gooch of Norfolk; of which he has given a draught, and which is preferable to a common splint, by its admitting the fingers to be more easily bent.

430
Of the os femoris,

"The position of the fractured os femoris should be on its outside, resting on the great trochanter; the pa-

tient's whole body should be inclined to the same side; the knee should be in a middle state, between perfect flexion and extension, or half-bent; the leg and foot, lying on their outside also, should be well supported by smooth pillows, and should be rather higher in their level than the thigh: one very broad splint of deal, hollowed out, and well covered with wool, rag, or tow, should be placed under the thigh, from above the trochanter quite below the knee; and another somewhat shorter should extend from the groin below the knee on the inside, or rather in this posture on the upper side. The bandage should be of the eighteen-tail kind; and when the bone has been set, and the thigh well placed on the pillow, it should not, without necessity (which necessity in this method will seldom occur) be ever moved from it again until the fracture is united: and this union will always be accomplished in more or less time, in proportion as the limb shall have been more or less disturbed.

"In the fracture of the fibula only, the position is ⁴³¹ Of the fractured fibula. not of much consequence; because, by the tibia remaining entire, the figure of the leg is preserved, and extension quite unnecessary: but still even here the laying the leg on its side, instead of on the calf, is attended with one very good consequence, viz. that the confinement of the knee, in a moderately bent position, does not render it so incapable of flexion and use afterward, as the straight or extended position of it does; and consequently that the patient will be much sooner able to walk, whose leg has been kept in the former posture, than he whose leg has been confined in the latter.

"In the fracture of both tibia and fibula, the knee ⁴³² Of the fractured tibia and fibula. should be moderately bent; the thigh, body, and leg, in the same position as in the broken thigh. If common splints be used, one should be placed underneath the leg, extending from above the knee to below the ankle, the foot being properly supported by pillows, bolsters, &c. and another splint of the same length should be placed on the upper side, comprehending both joints in the same manner; which disposition of splints ought always to be observed, as to their length, if the leg be laid extended in the common way; only changing the nominal position of them, as the posture of the leg is changed, and calling what is inferior in one case exterior in the other, and what is superior in one in the other interior."

Reduction of, or setting a compound fracture, is ⁴³³ Reduction of a compound fracture. the same as in the simple; that is, the intention in both is the same, viz. by means of a proper degree of extension, to obtain as apt a position of the ends of the fracture, with regard to each other, as the nature of the case will admit; and thereby to produce as perfect and as speedy union as possible.

The dressing necessary in a compound fracture is ⁴³⁴ Dressings two kinds, viz. that for the wound, and that for the necessary in limb. By the former, we mean to maintain a proper compound opening for the easy and free discharge of gleet, sloughs, matter, extraneous bodies, or fragments of bone; and this in such manner, and by such means, as shall give the least possible pain or fatigue, shall neither irritate by its qualities, nor oppress by its quantity; nor by any means contribute to the detention or lodgment of what ought to be discharged. By the latter, our aim should be the prevention or removal

Practice.

Practice.

val of inflammation, in order, if the habit be good, and all other circumstances fortunate, that the wound may be healed by what the surgeons call the *first intention*; that is, without suppuration or abscess; or, that not being practicable, that gangrene and mortification, or even very large suppuration, may be prevented, and such a moderate and kindly degree of it established as may best serve the purpose of a cure. The first, therefore, or the dressing for the wound, can consist of nothing better, or indeed so good, as soft dry lint, laid on so lightly as just to absorb the sanies, but neither to distend the wound, nor be the smallest impediment or obstruction to the discharge of matter. This lint should be kept clear of the edges, and the whole of it should be covered with a pledget spread with a soft easy digestive. The times of dressing must be determined by the nature of the case; if the discharge be small or moderate, once in 24 hours will be sufficient; but if it be large, more frequent dressing will be necessary, as well to prevent offence as to remedy the inconveniences arising from a great discharge of an irritating sharp sanies.

435
Of preventing violent pain, inflammation, &c.

The method of treating the limb, with a view to the prevention of such accidents and symptoms as pain, inflammation, and laceration of parts are likely to produce, is different with different practitioners; some using from the very first relaxing greasy applications, others applying medicines of a very different nature. Both these may be right conditionally, that is, according to different circumstances in the case; but they cannot be equally so in the same circumstances.

436
Of applying relaxing cataplasms, &c.

Many practitioners are accustomed to envelope compound fractures in a soft warm relaxing cataplasm from the very first, whether the limb be in a tense swollen state or not. This seems to be injudicious. When from neglect, from length of time passed without assistance, from misconduct or drunkenness in the patient, from awkwardness and unhandiness in the assistants, or from any other cause, a tension has taken possession of the limb, and it is become tumid, swollen, and painful, a warm cataplasm is certainly the best and most proper application that can be made; and that for very obvious reasons: the state of the parts under these circumstances is such, that immediate union is impossible, and nothing but a free and plentiful suppuration can dissipate or remove impending mischief: every thing, therefore, which can tend toward relaxing the tense, swollen, and irritable state of the parts concerned, must necessarily be right; the one thing aimed at (plentiful suppuration) cannot be accomplished without it. But when the parts are not in this state, the intention seems to be very different. To relax swollen parts, and to appease pain and irritation by such relaxation, is one thing; to prevent inflammatory distension and tumefaction is certainly another; and they ought to be aimed at by very different means. In the former, a large suppuration is a necessary circumstance of relief, and the great means of cure; in the latter it is not, and a very moderate degree of it is all that is required. The warm cataplasms, therefore, although it be the best application that can be made use of in the one case, is certainly not so proper in the other, as applications of a more discutient kind, such as mixtures of spirit-vini, vinegar and water, with crude sal-ammoniac, spirit. Min-

dereri, acet. litharg. and medicines of this class, in whatever form the surgeon may choose. By these, in good habits, in fortunately-circumstanced cases, and with the assistance of what should never be neglected, I mean phlebotomy and the general antiphlogistic regimen, inflammation may sometimes be kept off, and a cure accomplished, without large collections or discharges of matter, or that considerable degree of suppuration which, though necessary in some cases, and almost unavoidable in others, are, and must be, rather promoted and encouraged, than retarded or prevented, by warm relaxing applications of the poultice-kind.

Compound fractures in general require to be dressed every day; and the wounded parts not admitting the smallest degree of motion without great pain, perfect quietude becomes as necessary as frequent dressing. The common bandage, therefore (the roller), has always in this case been laid aside, and what is called the *eighteen-tailed bandage* substituted, very judiciously, in its place.

437
Bandage and splints for compound fractures.

Splints, that is, such short ones as are most commonly made use of in simple fractures, are by all forbidden in the compound; and that for the same reason which ought to have prevented them from having ever been used in the former, viz. because the probable good to be derived from them can be but little, and the probable mischief is obvious and considerable.

But although short splints are, for many reasons, palpably improper in both cases, yet those which reach from joint to joint comprehend them both; and, applied on each side of the leg only, are very useful both in the simple and in the compound fracture, as they may, thus applied, be made to keep the limb more constantly steady and quiet than it can be kept without them.

With regard to luxations, many engines have been invented in order to make as strong an extension as possible; but by attending to the principles laid down n° 238, it will be found that these extraordinary degrees of force can never be necessary. To give very particular directions concerning the reduction of luxations in all cases, would not only be very tedious, but in a great measure unnecessary; as, by comparing the joint supposed to be luxated with the sound one, every intelligent operator must know whether it is so or not; and, it being remembered always to keep the muscles of the part in as relaxed a state as possible, the business of the surgeon is, 1. To restore the luxated bone to its place, first by extension, and then by reduction with his hands. 2. To preserve and retain what is so replaced, in their natural position. And lastly, 3. To prevent and cure the several symptoms which usually attend. The reduction is used to be commodiously performed by placing the patient on a stool, table, bed, or the ground, as the surgeon shall think most suitable to the case. It is however to be observed here, that those luxations are most readily reduced on a stool, which happen in the jaw, clavicle, arm, or hand; on a table, such as happen in the vertebrae or thighs; on a bed, such as happen in the legs or feet; and lastly, those dislocations are most commodiously reduced on the floor which happen on the shoulder or vertebrae of the neck.

439
Of luxations.

The extension is to be made much after the same manner as in fractures; viz. the outer or lower part the extension.

439
Of making extension.

Practice.

of the dislocated limb is to be extended by an assistant, till the head of the disordered bone be found to correspond exactly with the sinus from whence it was luxated. This may be done by the hands: but, if they are not so convenient, the extension seldom fails of being so well made by a napkin, as to render the machinery delineated in such an ample manner by Oribasius, Parey, Andreas a Cruce, Scultetus, and others, generally unnecessary; since they can effect scarce any thing more, unless it be to terrify and discourage the patient in the extension, by their formidable show.

440 Of replacing the bone.
To replace the luxated bone again in its natural seat, the surgeon must regulate the assistant's extension, by ordering it to be strong enough, and in a right direction; in the mean time he is to compress the articulation gently with his hands and fingers, till he find the elapsd bone recover its right place.

441 Signs of a luxation completely reduced.
An accurate reduction of a luxation is known to have been effected by the same signs which attend the reduction of fractures. It is a good sign, 1. If the bone be heard to snap or crack in its reduction. 2. When the disordered limb is found to be of the same length with the sound one. 3. When the pains grow less. Or lastly, 4. When the limb can perform its usual motion.

In those cases where the luxation is accompanied with a fracture, the reduction must be put off till that is first set and joined; for the extension cannot be safely attempted till the fracture be well joined by a firm callus.

442 Of retaining the bones in their places.
After the bones have been pushed into their places from whence they were forced out, the next business is carefully to retain them there. But bones that are entire are much easier retained than those that have been broken: for the latter cannot be contained in their right posture without strict bandage and rest; whereas there is in the first case seldom much occasion for bandage, or any great rest: for thus, in fresh dislocations of the jaw, bones of the fingers, hands, cubitus, and humerus, the bone may be immediately reduced without further bandage or rest; because they are generally held firm enough by their proper ligaments and muscles. It seems rather more necessary to bend, extend, and gently move the limb sometimes, than to endanger its becoming stiff and immovable by a long inactivity. But when the luxation happens in the lower extremities, it seems better to let the patient rest a few days in his bed, moving the limb gently as soon as he finds it capable, and afterwards he may rise and walk cautiously with it.

443 Of bandages, &c. for luxated joints.
On the other hand, when the ligaments have been much stretched by a violent and long-continued distention, or have been rendered infirm by any other means, it seems altogether necessary to make use of some proper bandage, and to recommend rest to the patient, till the ligaments have regained their former strength. But here it must be also carefully observed, to let the disordered articulation sometimes have a little gentle motion, by an easy flexion and extension of the limb, to prevent any stiffness or other bad consequence from such a continued rest. In the mean time, it may not be improper to moisten the bandages and bathe the part with sp. vin. aq. hungar, or some other warm and strengthening spirit, by which means the liga-

ments are used to become very firm and strong. The bandages themselves should be neither too tight nor too loose. As for the application of plasters, which has been such a prevailing custom in these cases, it seems rather to be prejudicial than otherwise.

Practice.

SECT. IX. Of the Reduction of Hernia.

THE cure of a rupture is either perfect (called also *radical*), or imperfect, which is called *palliative*.

This distinction, which is just and true, and founded both on reason and experience, has frequently been misunderstood by the generality of mankind, and has therefore been the cause of much undeserved censure on the practitioners of surgery.

The truth is, that though the events are extremely different, yet the chirurgical means which are made use of in either case are exactly the same, viz. reduction of the protruded parts, and retention of them, when so reduced, by proper bandage. These sometimes, and in some circumstances, produce a perfect cure; at other times, and under other circumstances, prove only a palliative one: and this uncertainty of event being dependent on causes which a surgeon can neither foresee nor direct with any tolerable degree of certainty, should warn him against being too forward in making a promise.

The different treatment which ruptures may require being dependent on different circumstances attending the disease, we shall divide them into four classes; under which may be comprehended, not only all the kinds of hernias, but every particularity also with which they may happen to be distinguished.

1. Under the first, we reckon those which are capable of easy and immediate reduction, and are not attended by any troublesome or bad symptoms. 2. Under the second, those which have been so long down, that the contained parts are either so altered in form, or have contracted such adhesions and connections, as to be absolutely incapable of being reduced at all. 3. Under the third, we comprehend those in which such stricture has been made on the protruded parts, as to bring on pain, and produce such an obstruction in the intestinal canal, as to render immediate reduction necessary, but at the same time difficult. 4. And under the fourth, we shall place those in which the return of the parts by the mere hand is absolutely impracticable, and in which the patient's life can be saved only by a chirurgical operation.

I. The first is very frequently met with in infants, and sometimes in adults, and is too often neglected in both. In the former, as the descent seldom happens but when the infant strains to cry, and the gut is either easily put up or returns as soon as the child becomes quiet, it often is either totally unattended to, or an attempt made to restrain it only by a bandage made of cloth or dimity; and which, being ineffectual for such purpose, lays the foundation of future trouble and mischief.

This is in great measure owing to a common opinion, that a young infant cannot wear a steel truss; a generally prevailing error, and which ought to be corrected. There is no age at which such truss may not be worn, or ought not to be applied: it is, when well made, and properly put on, not only perfectly safe and easy, but the only kind of bandage that can be depended

444 Uncertain events attending hernia.

445 Different classes of them.

446 Of the ruptures of infants.

447 A steel truss worn at any age.

Practice.

Practice.

depended upon; and as a radical cure depends greatly on the thinness of the hernial sac, and its being capable of being so compressed as possibly to unite, and thereby entirely close the passage from the belly, it must therefore appear, that the fewer times the parts have made a descent, and the smaller and finer the elongation of the peritoneum is, the greater the probability of such cure must be.

The same method of acting must, for the same reasons, be good in every age in which a radical cure may reasonably be expected; that is, the prolapsed parts cannot be too soon returned, nor too carefully prevented from falling down again; every new descent rendering a cure both more distant and more uncertain.

448
Treatment of the patient after the hernia is reduced.

As soon as the parts are returned, the truss should be immediately put on, and worn without remission; care being taken, especially if the patient be an infant, to keep the parts on which it presses constantly washed, to prevent galling.

It can hardly be necessary to say, that the surgeon should be careful to feel that the truss fits, as his success and reputation depend on such care. A truss which does not press enough is worse than none at all, as it occasions loss of time, and deceives the patient or his friends; and one which presses too much, or on an improper part, gives pain and trouble, by producing an inflammation and swelling of the spermatic cord, and sometimes of the testicle.

449
Of the rup- tures of adults.

In adults, whose ruptures are of long standing, and accustomed to frequent descent, the hernial sac is generally firm and thick, and the aperture in the tendon of the abdominal muscle large. The freedom and ease with which the parts return into the belly, when the patient is in a supine posture, and the little pain which attends a rupture of this kind, often render the persons who labour under it careless; but all such should be informed, that they are in constant danger of such alteration in their complaint, as may put them into great hazard, and perhaps destroy them. The passage from the belly being open, the quantity of intestine in the hernial sac is always liable to be increased, and, when down, to be bound by a stricture. An inflammation of that portion of the gut which is down, or such obstruction in it as may distend and enlarge it, may at all times produce such complaints as may put the life of the patient into imminent danger; and therefore, notwithstanding this kind of hernia may have been borne for a great length of time, without having proved either troublesome or hazardous, yet as it is always possible to become so, and that very suddenly, it can never be prudent or safe to neglect it.

Even though the rupture should be of the omental kind (which, considered abstractedly, is not subject to that degree or kind of danger to which the intestinal is liable), yet it may be secondarily, or by accident, the cause of all the same mischief; for while it keeps the mouth of the hernial sac open, it renders the descent of a piece of intestine always possible, and consequently always likely to produce the mischief which may proceed from thence.

They who labour under a hernia thus circumstanced, that is, whose ruptures have been generally down while they have been in an erect posture, and which have either gone up of themselves or have been easily

put up in a supine one, should be particularly careful to have their truss well made and properly fitted; for the mouth of the sac, and the opening in the tendon, being both large and lax, and the parts having been used to descend through them, if the pad of the truss be not placed right, and there be not a due degree of elasticity in the spring, a piece of intestine will in some posture slip down behind it, and render the truss productive of that very kind of mischief which it ought to prevent.

II. In the second class we ranked those cases in which the parts constituting the hernia are found irreducible, but not in a state of inflammation, nor producing any troublesome or dangerous kind of symptoms.

This incapacity of reduction may be owing to several causes, but most frequently arises either from the largeness of the quantity of the contents, from an alteration made in their form and texture, or from connections and adhesions which they have contracted with each other, or with their containing bag.

Ruptures are sometimes rendered difficult to be reduced, by that portion of the intestinal canal which is called the *cæcum*, or the beginning of the colon, being contained in the hernial sac. When a hernia of this kind (*viz.* one containing a part of the intestinal tube) has been long neglected, and suffered to remain in the scrotum without any bandage at all to support its weight, the hernial sac being constantly dragged down, and kept in a state of distention, necessarily becomes thick, hard, and tough: by this means the diameter of its neck is lessened, and the return of the intestine back from the scrotum into the belly rendered more and more difficult, as the parts through which it is to pass become harder and less capable of yielding. This will indeed, in time, prove an obstruction sufficient to hinder any part of the intestine, or even of the omentum, from being returned; but the more the difficulty is, which proceeds from the mere figure and size of the portion of gut, the greater will be the obstruction when added to that arising from the just-mentioned cause.

An alteration produced by time, and constant, though gentle pressure, in the form and consistence or texture of the omentum, is also no infrequent cause why neglected omental ruptures become irreducible.

The cellular membrane, in all parts of the body, however loose and light its natural texture may be, is capable of becoming hard, firm, and compact, by constant pressure. Of this there are so many and so well known instances, that it is quite unnecessary to produce any.

The omentum, from its texture, is liable to the same consequence. When a portion of it has been suffered to remain for a great length of time in the scrotum, without having ever been returned into the belly, it often happens, that although that part of it which is in the lower part of the hernial sac preserves its natural soft, adipose, expansive state, yet all that part which passes through what is called the *neck of the sac*, is, by constant pressure, formed into a hard, firm, incompressible, carnosous kind of body, incapable of being expanded, and taking the form of the passage in which it is confined, exactly filling that passage, and rendering it impossible to push up the loose part which fills the scrotum.

The

450
Why some ruptures cannot be reduced.

The same reason for incapacity of reduction is also sometimes met with in ruptures of the intestinal kind, from an alteration produced on that part of the mesentery which has been suffered to lie quiet for a great length of time in the neck of an old hernial sac.

The other impediment to the return of old ruptures, is connection and adhesion of the parts, either with each other, or with the bag containing them. This is common to both the intestinal and omental hernia, and is produced by slight inflammations of the parts, which have been permitted to lie long in contact with each other, or perhaps, in many cases, from the mere contact only. These adhesions are more or less firm in different cases; but even the slightest will almost always be found an invincible objection to the reduction of the adherent parts by the hand only.

Many, or perhaps most, of these irreducible ruptures, become so by mere time and neglect, and might at first have been returned; but when they are got into this state, they are capable of no relief from surgery but the application of a suspensory bag, to take off or lessen the inconvenience arising from the weight of the scrotum.

451
Directions to people who have irreducible ruptures.

People in this situation should be particularly careful not to make any attempts beyond their strength, nor aim at feats of agility; they should take care to suspend the loaded scrotum, and to keep it out of the way of all harm from pressure, bruise, &c. When the tumour is very large, a soft quilted bolster should be worn at the bottom of the suspensory to prevent excoriation, and the scrotum should be frequently washed for the same reason; a loss of skin in this part, and in such circumstances, being sometimes of the utmost importance. They ought also to be particularly attentive to the office of the intestinal canal, to see that they do not, by any irregularity of diet, disorder it, and keep themselves from being constipated, for reasons too obvious to need relating. By these means, and with these cautions, many people have passed their lives for many years free from disuse or complaint, with very large irreducible ruptures.

On the other hand, it is fit that mankind should be apprised, that the quiet inoffensive state of this kind of hernia is by no means to be depended upon; many things may happen to it, by which it may be so altered, as to become hazardous and even fatal: an inflammation of that part of the gut which is down, any obstruction to the passage of the aliment or feces through it, a stricture made by the abdominal tendon, either on what has been long down or on a new portion which may at any time be added to it, are always capable of so altering the state of the case, as to put the life of the patient into danger.

Indeed the hazard arising from a stricture made on a piece of intestine contained in the sac of an old irreducible hernia, is, in one respect, greater than that attending one that has been found at times reducible; since, from the nature of the case, it will hardly admit of any attempt toward relief but the operation; and that, in these circumstances, must necessarily be accompanied with additional difficulty.

Among the ruptures which have been thought not reducible, and treated as such, there have been some which, upon more judicious and more patient attempts, have been found capable of reduction.

When this is suspected to be the case, the proper method is by absolute rest, in a supine posture, for a considerable length of time, and by great abstinence and the use of evacuates, so to lessen the size of the parts in the hernial sac, as to render them capable of passing back again into the belly.

This method has now and then succeeded, and in some cases is worth the trying; but, previous to the attempt, there should be some circumstances which makes success probable; and there should also be good reason to believe, that the habit and age of the patient will bear the necessary confinement and evacuation; otherwise, even though he should get rid of his rupture, he may be much worried by the experiment.

If such attempt succeeds, a truss should be immediately put on, and worn constantly without remission; for in these people, the largeness of the abdominal aperture, the thickness of the hernial sac, and the relaxation of the mesentery, make a new descent always to be apprehended and guarded against.

An omental rupture, which has been so long in the scrotum as to have become irreducible, is very seldom attended with any bad symptoms, considered abstractedly; but it is constantly capable of being the occasion of an intestinal hernia and all its consequences; neither is that all; for the omentum, either so altered in form and texture, or so connected as to be incapable of reduction, may by accident inflame, and either become gangrenous or suppurate, and be the occasion of a great deal of trouble.

453
III. Under the third division, we reckon those ruptures of the intestine which are reducible, but whose reduction is difficult, and which are attended with pain, trouble, and hazard.

Difficulty of reduction may be owing to several causes. The size of the piece of omentum, or the inflamed state of it; the quantity of intestine and mesentery, an inflammation of the gut, or its distention by feces or wind; or the smallness of the aperture of the tendon through which the hernia passes. But to whatever cause it be owing, if the prolapsed body cannot be immediately replaced, and the patient suffers pain, or is prevented thereby from going to stool, is called an *incarcerated hernia*, a *strangulated hernia*, or a *hernia with stricture*.

Every symptom which attends an incarcerated rupture depends on this stricture, and is justly accountable for from it. The tumour, the pain, the tension of the belly, the nausea, the vomiting, and the suppression of stools, are so many effects produced by it, and removable only by removing it. In order to effect a reduction, the patient should be laid in a supine posture, with his trunk certainly as low, if not lower, than his thighs; the thigh on the diseased side should be so elevated as to contribute as much as possible to the relaxation of the abdominal aperture; and then the surgeon, grasping the lower part of the tumour gently with his hand, in such a manner as to keep the testicle from ascending, and the intestine from descending, must endeavour to procure the return of the latter through the ring, as it is vulgarly called, by gentle continued pressure toward that opening. If the case be a bubonocoele, there will be no occasion for endeavouring to grasp the tumour, but, by continued moderate pressure on it with the fingers, to endeavour the return of the piece of gut.

453
Method of attempting the reduction of an old hernia.

454
Method of attempting the reduction of a strangulated hernia.

Practice.

This may serve for a general description of the method of performing this operation; but the exact manner of executing it is one of those manœuvres which can be learnt only by observation and practice, and of which no verbal description can convey an adequate and perfect idea: knowledge of the structure and situation of the parts will instruct any one how to go about it; and a little practice will soon make him adroit.

455
Of the posture of the body.

The posture of the body, and the disposition of the lower limbs, may be made very assiduous in this operation when the difficulty is considerable: the nearer the posture approaches to what is commonly called standing on the head, the better, as it causes the whole packet of small intestines to hang, as it were, by the strangulated portion, and may thereby disengage it. A little time and pains spent in this manner will frequently be attended with success, and obtain a return of the part; but if it should not, and the handling of it (which should always be gentle) becomes painful and very fatiguing to the patient, we are advised to desist a few hours, and try the effect of other means, viz. phlebotomy, glysters, &c. But when all these have failed, there is then no other resource than in a surgical operation; and perhaps there is not in the practice of surgery a point which requires more judgement, firmness, or delicacy, than to determine the precise time beyond which this operation should not be deferred, and for a surgeon to conduct himself so as to induce a patient to submit to it early enough for his preservation. The time in which a piece of gut will become gangrenous from stricture, or get into a state approaching to that of a gangrene, is extremely uncertain, and depends on circumstances which no man can foresee. There have been several instances of ruptures, attended by pressing symptoms of stricture, which have been safely returned by the hand only, at the end of several days; or the operation having been performed at the same distance of time, the parts have been found sound and unhurt: on the other hand, there are many instances producible, of the intestine having been with great difficulty replaced, or of its returning of its own accord, from being mortified, or (the operation having been submitted to) of its having been found in such state by the operator at the end of not many hours.

456
Operation not to be very much dreaded.

The two principal circumstances which have most contributed to the infrequency of performing this operation, are, a dread of great hazard from the operation itself, considered abstractedly; and a fear of bringing a disgrace upon it, by having performed it too late. The first of these is vastly greater than it ought to be, and is most frequently the cause of the latter: so that if the one can justly be lessened, the other will not be so likely to happen.

457
Of the time when it should be performed.

Mr Pott is of opinion, that the operation ought always to be performed as soon as possible, after it appears that all rational attempts, by large and free bleeding, the warm bath, glysters, &c. are found to be ineffectual, or that the symptoms rather increase than decrease while such means are made use of, and that the handling necessary for reduction becomes more and more painful: for if it be delayed until the inflammation has attained a certain height, though the parts, upon being laid open, are not found

Vol. X.

quite gangrenous, that is no proof that the want of success must be set to the account of the operation merely. That state of inflammation, either of the intestine or of the hernial sac, which is just not gangrenous, is no state of safety, nor are we sure that removing the stricture will at this time appease the symptoms or abate the hazard; far from it: such an alteration may have already been made in the intestine that a mortification will ensue, though it be set free and returned into the belly. A ligature need not be continued around any part of a living animal, until it becomes quite gangrenous, in order to produce its destruction; there is a certain point of time in which the circulation is so prevented, that the same event will follow, though the ligature be then removed. It is indeed a nice, and no very easy matter, to find this precise time; but this difficulty and uncertainty are the strongest reasons for anticipating rather than waiting for it: for when, in the present case, such time arrives, or is nearly arrived, the risk of the operation becomes complicated with that arising from the diseased state of the parts within; and the chance of success is thereby much lessened.

When the operation shall be thought necessary, the manner of performing it is as follows.

458
Manner of performing it.

The pubes and groin having been clean shaved, the patient must be laid on his back on a table of convenient height, with his legs hanging easily over the end of it; then with a straight dissecting knife an incision must be made through the skin and membrana adiposa, beginning just above the place where the intestine passes out from the belly, and continuing it quite down to the lower part of the scrotum. Upon dividing the adipose membrane, there generally appear a few small distinct tendinous kind of bands, which lie close upon the hernial sac, which must be divided also as well as the sac: the same knife with which the incision through the skin was made will execute this; which should be done with a steady hand and great caution, it being of very different degrees of thickness in different cases. In the bubonocoele, or that which is confined to the groin, the sac is most frequently thin, consequently more easily divided, and requires greater attention in the operator. In the ocheocele, or scrotal hernia, if it be recent, the sac is usually thin also; if ancient, it is sometimes of considerable thickness: but whatever be the state of it, if the operator has any doubt, let him, as soon as he has made a small puncture in what appears to him to be the hernial sac, endeavour to introduce a probe into it: this will give him the necessary satisfaction; for if he has not pierced the sac, the probe will be stopped by the cells of the common membrane; and if he has, it will pass in without any obstruction. The place to make the incision in the hernial sac is about an inch and half below the stricture; and the opening need not be larger than just to admit the end of the operator's fore-finger; which, considering the great dilatibility of these membranes, will be a very small one. The fore-finger introduced into this aperture is the best of all directors; and upon that a narrow-bladed curved knife, with a bold probe point, will be the only instrument necessary to finish the operation. With this knife on the finger (the point of the former being

42 F

always

Practice.

Practice.

always short of the extremity of the latter) the sac must be divided quite up to the opening in the tendon, and down to the bottom of the serotum.

Upon the first division of the sac, a fluid generally rushes out; which fluid is different in quantity, colour, and consistence, according to the date, size, and some other circumstances attending the rupture.

This fluid has sometimes been mentioned as a defence against an accident from the knife in the first division of the hernial sac, as if it kept the intestine at such a distance as thereby to lessen the hazard of its being wounded: but this is a very fallacious circumstance, and never to be trusted: the security of this operation depends entirely on a competent knowledge of the parts, a steady hand, and an attentive eye.

Different operators, especially among the French, have proposed a number of different instruments for the safe performance of this incision; as the bistouri cachée, the bistouri herniare, the winged director, the blunt scissars, &c. &c. all which are calculated for the defence and preservation of the intestine in the division of the sac and tendon: but whoever will make use of the two knives just mentioned, will find, that he will never stand in need of any other instrument, and that he will with them be able to perform the operation with more ease to himself, with less hazard to his patient, and with more (A) apparent dexterity, than with any other whatever.

"The sac being laid open, the intestine generally pushes out immediately (unless it is confined by being enveloped in the omentum), and appears to be much more in quantity than it seemed to be while it was confined within the serotum.

459
Of dividing
the tendon.

This is the time to try whether, by gently drawing out a little more of the gut, its bulk cannot be so reduced as to enable the surgeon to return it back into the belly without dividing the tendon. In the case of the protrusion of a very small piece of intestine, it has been found practicable; the difficulty of returning a large portion arising principally from the quantity of mesentery engaged in the stricture: and indeed, tho' it may now and then happen that a small piece of gut may be returnable without a division of the tendon, yet if it cannot be very easily accomplished, it had better not be attempted, since, in the state in which this part must necessarily be, to require the operation thus far, any degree of force used to it will most probably be more prejudicial and hazardous than the rest of it, if performed properly with a knife.

An attention to the natural structure, figure, and direction of the parts, will give us the best informa-

tion how to make the division of the stricture to the best purpose and with the least hazard.

The tendon of the obliquus descendens muscle runs in an oblique direction from above downward; and the natural opening which is always found in it, and through which the hernia passes, is made by a kind of separation of the fibres from each other: the direction of this opening is the same as that of the tendon, that is, obliquely downward from the os ilion to the os pubis: the knife, therefore, should be so managed, as rather to continue this separation than to make any transverse section: its edge should be applied to the superior and posterior part of the oval, and carried upward and obliquely backward, until a sufficient opening is made to serve the purpose. By this means, the fibres of the tendon will be rather separated from each other than cut; and, in all probability, the risk arising from the incision will be lessened.

It is generally advised to make the division of the stricture free and large, as well to admit the easy return of the parts, as to prevent the inconvenience which it is supposed will be more likely to attend a small wound in a tendinous body than a large one.

The first intention, the easy return of the intestine, should certainly be fulfilled; and therefore the incision ought always to be large enough for that purpose, and to afford an opportunity of passing the end of the finger round on the inside in case of any adhesion: but as too large an opening may be attended with very ill consequence, it ought also to be guarded against. In the majority of cases, a small incision will be found sufficient for the purpose of reduction; and where the parts are free from adhesion, and the safe return of them is the only object of attention, a small division, made in the manner already directed, is not liable to any more pain or trouble than a large one, and may therefore be safely trusted.

461
Of the state
of the in-
testines.

The sac and stricture being laid open and divided, the contained parts come into view; and, according to the different circumstances of the rupture and of the patient, will be found in different states, and require different treatment.

These states are reducible to three general heads: that is, the contained parts will be found either in a sound, healthy, loose, unconnected state, and fit for immediate reduction; or in a sound state, but, from some particular circumstances, incapable of being immediately replaced; or in an unsound diseased state, and requiring to be treated accordingly.

If the rupture consists of a piece of intestine only, and that neither mortified nor adherent, the sooner it

19

(A) They who are not accustomed to perform operations of such consequence as this is, are apt, from timidity, to be too sparing in making their external incision; by which means, they add considerably to their own embarrassment, and to the fatigue of the patient. A free division of the hernial sac and serotum downwards, gives room for the more easy admission of the finger into the stricture in order to divide it, and affords an opportunity of handling the intestine or omentum more gently as well as more properly in order to return them into the belly; both which necessary parts of the operation are much impeded by a small incision.

As therefore no possible advantage can arise from a small wound, but on the contrary it may be attended with great inconvenience both to the patient and surgeon, Mr Pott advises, when such an opening is made in the hernial sac, as will admit the operator's fore-finger, and upon it his knife, that he immediately divide the sac and serotum down to the bottom. It is true, that, upon such division, the quantity of intestine will seem to be increased; and an ignorant bystander may be alarmed at this fallacious appearance, which is produced merely by the confined compressed gut being set free, and not by the addition of any more. The advantage which will arise to the operator, and consequently to the patient, from such division, is real and great; it will enable the former to finish his work with freedom, and spare the latter a great deal of pain.

Practice. is returned, the better; and the more gently it is handled for reduction, the better also.

If the intestine be accompanied with a portion of omentum, the latter (if in a proper state) should be returned first.

In returning the intestine, care should be taken to endeavour to put in that part first which came out last, otherwise the gut will be doubled on itself, and the difficulty and trouble be thereby much increased; and in making the reduction, the fingers should be applied to that part of the intestine which is connected with the mesentery, rather than its convex part, as it will both serve the purpose better, and be less likely to do mischief.

While the reduction is making, the leg and thigh on the ruptured side should be kept elevated; as such position of the limb will much facilitate the return of the parts.

Long confinement in the scrotum will in some people produce slight adhesions by slender filaments, which are generally very easily separated by the finger, or divided by a knife or scissars, whether the adhesions be of the parts of the intestine *inter se*, or to the hernial sac. If the adhesion be of the former kind, and such as proves very difficult to separate, it will be better to return the gut into the belly as it is, than to run the risk of producing an inflammation by using force: if it be of the latter, that is, if the connection be with the sac, there can be no hazard in wounding that; and therefore it may be made free with.

SECT. X. Of the Fistula in Ano.

The *fistula in ano* is an abscess running upon or into the intestine rectum.

If the surgeon have the first management of the abscess, and there appear an external inflammation upon the one side of the buttock only; after having waited for the proper maturity, let him with a knife make an incision the whole length of it; and in all probability, even though the bladder be affected, the largeness of the wound, and the proper application of doסים lightly pressed in, will prevent the putrefaction of the intestine, and make the cavity fill up like imposthumations of other parts.—If the sinus be continued to the other buttock, almost surrounding the intestine, the whole course of it must be dilated in like manner; since, in such spongy cavities, a generation of flesh cannot be procured but by large openings; whence also, if the skin is very thin, lying loose and flabby over the sinus, it is absolutely necessary to cut it quite away, or the patient will be apt to sink under the discharge, which is sometimes excessive.

Here we have considered the imposthumation as possessing a great part of the buttock; but it more frequently happens, that the matter points with a small extent of inflammation on the skin, and the direction of the sinus is even with the gut: in this case, having made a puncture, you may with a probe learn if it has penetrated into the intestine, by pressing your finger up it, and feeling the probe introduced through the wound into its cavity; though, for the most part, it may be known by a discharge of matter from the anus. When this is the state of the fistula, there is no hesitation to be made; but immediately putting one blade of the scissars up the gut, and the other up the

wound, snip the whole length of it. This process is as advisable when the intestine is not perforated, if the sinus is narrow, and runs upon or very near it; for if the abscess be tented, which is the only way of dressing it while the external orifice is small, it will almost certainly grow callous: so that the surest means of cure will be opening the gut, that proper applications may be laid to the bottom of the wound. However, it should be well attended to, that some sinuses pretty near the intestine neither run into nor upon it; in which case, they must be opened, according to the course of their penetration. There are abundance of instances, where the intestine is so much ulcerated, as to give free issue to the matter of the abscess by the anus: but there are none where there is not, by the thinness and discoloration of the skin, or an induration to be perceived through the skin, some mark of its direction; which, if discovered, may be opened into with a lancet, and then it becomes the same case as if the matter had fairly pointed.

If the sinuses into and about the gut are not complicated with an induration, and you can follow their course, the mere opening with scissars, or a knife guided on a director, will sometimes suffice; but it is generally safer to cut the piece of flesh surrounded by these incisions quite away, and, when it is callous, absolutely necessary, or the callosities must be wasted afterwards by escharotic medicines, which is a tedious and cruel method of cure.

When the fistula is of a long standing, and we have choice of time for opening it, a dose of rhubarb the day before the operation will be very convenient, as it not only will empty the bowels, but also prove an astringent for a while, and prevent the mischief of removing the dressings in order to go to stool.

It sometimes happens, that the orifices are so small, as not to admit the entrance of the scissars; in which case, sponge-tents must be employed for their dilatation.

In performing these operations on the anus, no instruments are so handy as the knife and scissars; almost all the others which have been invented to facilitate the work are not only difficult to manage, but more painful to the patient: however, in those instances where the fistula is very narrow, and opens into the intestines just within the verge of the anus, the syringotomy may be used with advantage; but where the opening into the gut is high, it cannot be employed without giving great pain.

The worst species of fistula is that communicating with the urethra, and sometimes (though the prostate gland) with the bladder itself. This generally takes its rise from a former gonorrhoea, and appears externally first in *parino*: afterwards, increasing more towards the anus, and even sometimes into the groin, it bursts out in various orifices, through the skin, which soon becomes callous and rotten; and the urine passing partly through these orifices, will often excite as much pain, and of the same kind, as a stone in the bladder.

This species of fistula taking its rise from strictures of the urethra, is only manageable by the bougie: for so long as the urethra is obstructed, the cure of the fistula will be imperfect; but if the canal be opened by this application, it is amazing what obstinate indurations and foul sinuses will in consequence disappear;

though there are some so callous and rotten, as to demand the knife and skillful dressings, notwithstanding the urethra should be dilated by the use of bougies.

SECT. XI. *Bronchotomy, the Extirpation of the Tonfils, &c.*

§ 1. *Of Bronchotomy.*

THE operation of bronchotomy is an incision made in the aspera arteria, to make way for the air into the lungs, when respiration is obstructed by any tumour compressing the larynx, or some other disorder of the glottis and aspera arteria, without any apparent tumour.

The manner of doing it, is by making a longitudinal incision through the skin, three quarters of an inch long, opposite to the third and fourth ring of the trachea, if you have the choice of place; and when you cannot make it so high, the rule will be to wound a little below the tumour: it is always advised to pinch up the skin for this process, which, however, may be left to the discretion of the surgeon. When the skin is cut through, you must make a small transverse incision into the wind-pipe, and immediately introduce a silver crooked canula near half an inch long, with a couple of little rings at the top of it, through which a ribband may be passed round the neck, to keep it fixed in the wound.

The method of dressing will be easily understood; since, after the patient can breathe by the natural passage, if you withdraw the hollow tent, the wound will become a simple one, and, notwithstanding its penetration through a cartilage into a large cavity, require a superficial application only.

§ 2. *Extirpation of the Tonfils, and large Piles.*

THE tonfils sometimes grow so large and scirrhus as to become incurable, and even to threaten suffocation, if not extirpated. The manner of doing this operation formerly, was by cutting them off: but the almost constant consequence of this wound was a violent hæmorrhagy which sometimes proved mortal; on which account it is rejected in favour of the ligature, which is not only void of danger, but also seldom fails of cure.

If the basis of the tonsil is smaller than the upper part, you may pass the ligature by tying it to the end of a probe, bent into the form of an arch, and set into a handle; which being carried beyond the gland, and round it, is to be brought back again: this done, you may easily tie it by the means of an instrument of Mr Cheselden's contrivance, which holds one end of the string on the side of the tonsil next the throat, while you make the knot by pulling the other with the right-hand quite out of the mouth, as will be easily understood by the draught in the copper-plate. Should it happen that the tonsils are conical, so that the ligature will necessarily slip over its extremity when we attempt to tie; in this case, he has recommended an instrument like a crooked needle, set in a handle, with an eye near the point, threaded with a ligature, which is to be thrust through the bottom of the gland, and being laid hold of with a hook, the instrument is to be withdrawn; then, pulling the double ligature forwards, it must be divided, and one part

be tied above, and the other below the tumour; the knots are to be always double, and the ligature to be cut off pretty near them. If after four or five days they slip, or seem to have mortified the tonsil only in part, you must repeat the whole operation; and if it fail a second time, you must even repeat it again.

This kind of extirpation is more practised in large piles that are esteemed incurable. When the piles are within the intestine, you must place your patient over a fomentation in a clofestoof, and have a crooked needle with a double ligature ready to pass through them, when by drawing they are pushed out of the anus (for sometimes the intestine will return suddenly), and tie above and below as in the instance of the tonsil. Sometimes the piles are of that shape as to admit a single ligature to be tied round them without the help of a needle, which is less painful. If there are several, you must only tie one or two at a time; for the pain of the ligature is excessive, and would be intolerable if many were tied at once: however, every five or six days, the operation may be repeated till all are extirpated, and the parts must be kept supple by some emollient ointments.—When the piles are small, they may safely and with much less pain be cut off.

The uvula is subject to so great a degree of relaxation sometimes, that it almost chokes the patient: the readiest cure is cutting off all but half an inch of it; which may be done at one snip with a pair of scissors (particularly curved for that purpose), laying hold of it with a forceps, lest it should slip away.

§ 3. *Of the Polypus.*

THE polypus of the nose is said to be an excrescence of flesh, spreading its branches amongst the laminae of the os ethmoides, and through the whole cavity of one or both nostrils. It happens very often to both sides of the nose at once: and in that case is very troublesome, almost suffocating the patient, at least making respiration very difficult. The intent of the operation is the removal of this obstacle.

Polypi arise from the membrane spread upon the laminae spongiosae, pretty nearly in the same manner as the hydatids of the abdomen, in one kind of dropsy, do from the surface of the liver; or as ganglions from the tendons, borrowing their coats from a production of its fibres and vessels. If they appear soft, and of the colour of the serum of the blood, in all likelihood they are formed of such a sort of water contained in cysts, which, upon breaking the membrane, leaves a little hold for the instrument, that but a small part of it can be extracted afterwards. This polypus is to be left to harden, before the operation be undertaken, which in process of time it generally will do. In the next degree of consistence, they retain pretty nearly the same colour, and are often partly watery, and partly of a viscid texture, which, though not tenacious enough to admit of drawing them out by the roots, may at several attempts be taken away by bits. The next degree of consistence, is that which is neither so soft as to be squeezed to pieces, nor so hard and brittle as to crumble, or adhere to the membrane with that force as not to admit of separation: this is the most favourable one. The last is hard and scirrhus, adhering

Practice. so tight as to tear rather than separate in the extraction, and sometimes even tends to degenerate into a cancer. This polypus is very difficult of cure.

The polypus sometimes dilates to that degree, as not only to extend beyond the os palati, and hang over the œsophagus and trachea; but also spreading into the sinus maxillaris, so exactly fills up every interstice of the nose, as to obstruct the lower orifice of the *ductus ad nasum*, and prevent the descent of the tears, which necessarily must return through the puncta lachrymalia: and sometimes they grow so enormously large, as even to alter the shape of the bones of the face.

When the polypus appears in the throat, it is always advisable to extract it that way; it being found, by experience, more ready to loosen when pulled in that direction, than by the nose. To this end, it would be right, before undertaking the operation, to let your patient lie on his back two or three hours, which will bring it still further down; for the body of the polypus does not universally adhere, and will by its weight stretch out the fibres by which it is connected to the nose; nay, there are instances, where by a little effort, such as hawking, they have dropt quite off.

The method of extracting it is by a pair of forceps, with a slit at their extremities for the better hold; which must be introduced into the nostril about an inch and a half, to make more sure of it towards the roots; then twisting them a little from one side to the other, you must continue in that action, while you pull very gradually the body of the polyps. If it break, you must repeat the extraction as long as any remains, unless it is attended with a violent hæmorrhagy, which is an accident that sometimes follows upon the operation, and seldom fails when the excrescence is scirrhus. However, the surgeon is not to be alarmed at the appearance of an immoderate effusion the moment after the separation: for, generally speaking, the vessels collapse very soon again; but if they do not, dry lint, or lint dipt in some styptic, will readily stop it.

After the extirpation, it has been usual, in order to prevent a relapse, to dress with escharotic powders, and even to burn with the actual cautery; but neither the one or the other can be of great service in this case, and both are painful and dangerous. If ever the use of corrosive medicines is advisable, it should be for destroying the remainder of a polypus which cannot all be taken away; and then the escharotics may be better conveyed to the part by a long tent, than a seton passed through the nose and mouth, which is difficult to do without hurting the patient, and very nasty to bear.

§ 4. Of the Hare-lip.

THIS is a fissure in the upper lip, with want of substance; and is a natural defect, the patient being always born with it, at least that species of hare-lip which requires the following operation. The cure is to be performed by the twisteduture. There are many lips where the loss of substance is so great, that the edges of the fissure cannot be brought together, or at best where they can but just touch; in which case the attempt should be forborn: it

is likewise forbidden in infants, and with reason if they suck; but otherwise it may be undertaken with great safety, and even with more probability of success than in others that are older. It is not uncommon for the roof of the mouth to be fissured likewise; but this is no objection to the operation, if the skin of the lip is loose enough to admit of reunion: and it may be remarked, that the fissure of the palate, in length of years, closes surprisingly in some cases.

The manner of performing the operation is this. You first with a knife separate the lip from the upper jaw, by dividing the frænulum between it and the gums; and if the dentes incisivi project, as is usual in infants, they must be cut out with the same knife: then with a thin pair of straight scissors take off the callous edges of the fissure the whole length of it; observing the rule of making the new wound in straight lines, because the sides of it can never be made to correspond without this caution. The two lips of the wound being brought exactly together, pass a couple of pins, one pretty near the top, and the other as near the bottom, through the middle of both edges of it, and secure them in that situation by twisting a piece of waxed thread cross and round the pins seven or eight times; you must then cut off the points, and lay a small bolster of plaster underneath them, to prevent their scratching; but when the lower part only of the hare-lip can be brought into contact, it will not be proper to use more than one pin.

The practice of bolstering the cheeks forward does little or no service to the wound, and is very uneasy to the patient. The manner of dressing will be, to remove the applications, which are quite superficial, as often only as is necessary for cleanliness. The method is to dress the three first days, and afterwards to do it every day, or every other day: it is not at all requisite to dress between the jaw and lip where the frænulum was wounded, there being no danger that an inconvenient adhesion should ensue. In about eight or nine days the parts are usually united, and in children much sooner; when you must gently cut the threads, and draw out the pins, applying upon the orifices a piece of plaster and dry lint. It will be proper, in order to withdraw the pins more easily, to daub the ligatures and pins with warm water, and also moisten them with sweet oil, two or three days before you remove them; which will wash off the coagulated blood, that would otherwise fasten them so hard to the ligature as to make the extraction painful.

§ 5. Of the Wry Neck.

THE operation of cutting the wry neck is very uncommon, and is never to be practised but when the disorder is owing to a contraction of the maltoideus muscle only; as it can answer no purpose to fet that muscle free by dividing it (which is all that is to be done) if the others in the neck are in the same state; and more especially if it has been of long standing from infancy, because the growth of the vertebrae will have been determined in that direction, and make it impossible to fet the head upright.

When the case is fair, the operation is this. Having laid your patient on a table, make a transverse incision through the skin and fat something broader

than the muscle, and not above half an inch from the clavicle; then passing the probed razor with care underneath the muscle, draw it out and cut the muscle. The great vessels of the neck lie underneath; but when we are aware of their situation, the danger of wounding them may be avoided. After the incision is made, the wound is to be crammed with dry lint, and always dressed so as to prevent the extremities of the muscle from reuniting; to which end, they are to be separated from each other as much as possible by the assistance of a supporting bandage for the head during the whole time of the cure, which will generally be about a month.

468

§ 6. Of the Phymosis.

THE *phymosis* signifies no more than such a straitness of the prepuce that the glans cannot be denuded; which if it becomes troublesome, so as to prevent the egress of the urine, or conceal under it chancres or foul ulcers, quite out of the reach of application, is to be cut open. It sometimes happens that children are born imperforate; in which case, a small puncture, dressed afterwards with a tent, effects a cure. But this operation is chiefly practised in venereal cases, in order to expose chancres either on the glans or within-side the prepuce itself: And here, if the prepuce is not very callous and thick, a mere incision will answer; which may be made either with the scissars, or by slipping a knife between the skin and glans to the very extremity, and cutting it up. The last method is more easy than that of the scissars: but it is safer to make the wound on the side of the prepuce than upon the upper part, for sometimes the great vessels on the dorsum penis afford a terrible hæmorrhage; though as the prepuce remains better shaped after an incision made in the upper part, the upper incision is to be preferred by those who understand how to take up the vessels. In children, it sometimes happens that the prepuce becomes very much contracted; and in that case, it is accidentally subject to slight inflammations, which bring on some symptoms of the stone; but the disorder is always removed by the cure of the phymosis.

If the prepuce be very large and indurated, the opening alone will not suffice: it is more advisable to take away the callosity by circumcision, which must be performed with a knife; and if the artery bled much, it must be taken up with a small needle and ligature.

469

§ 7. Of the Paraphymosis.

THE *paraphymosis* is a disease of the penis, where the prepuce is fallen back from the glans, and cannot be brought forwards to cover it. There are many whose penis is naturally thus formed, but without any inconvenience; so that since the time of the Romans (some of whom thought it indecent to have the glans bare), it has not been usual to perform any operation upon that account; but we read the several processes of it described very particularly by Celsus, who does not speak of it as an uncommon thing. Most of the instances of this distemper are owing to a venereal cause; but there are some where the prepuce is naturally very tight, which take their rise from a sudden contraction of it, and immediate enlargement of the

glans preventing its return. Sometimes it happens that the surgeon succeeds in the reduction immediately, by compressing the extremity of the penis at the same time he is endeavouring to advance the prepuce; if he does not, let him keep it suspended, and attempt again, after having fomented and used some emollient applications: but if, from the contraction below the corona glandis, there is so great a stricture as to threaten a gangrene, or even, if the penis is much enlarged by water in the membrana reticularis, forming tumours called *crystallines*, three or four small incisions must be made with the point of a lancet into the stricture and crystallines, according to the direction of the penis; which, in the first case, will set free the obstruction, and in the other evacuate the water. The manner of dressing afterwards must be with fomentations, digestives, and the theriaca Londinensis over the pledgits.

§ 8. Puncture of the Perineum.

470

THIS operation is performed, when the bladder is under such a suppression of urine as cannot be relieved by any gentler methods, nor, by reason of the obstruction in its neck or the urethra, will admit of the introduction of a catheter. The manner of doing it, as described by most writers, is by pushing a common trocar from the place where the external wound in the old way of cutting is made, into the cavity of the bladder, and so procuring the issue of the water through the canula: but others, refining upon this practice, have ordered an incision to be carried on from the same part into the bladder, and then to insinuate the canula. But both the methods are to be rejected in favour of an opening a little above the os pubis: for besides that it is not easy to guide the instrument through the prostate gland into the bladder, the necessity of continuing it, in a part already very much inflamed and thickened, seldom fails to do mischief, and even to produce a mortification.

There is another method still more easy both to the patient and the operator; which consists only in emptying the bladder with a common trocar, and stopping the canula with a little cork, which is afterwards to be taken out as often as the patient has occasion to urinate. The canula is to be continued in the bladder till such time as the person finds he can void his urine by the natural passage.

In this operation the abdomen ought to be perforated about two inches above the os pubis; and if the patient be fat, the trocar should penetrate two inches, otherwise an inch and a half will be sufficient.

§ 9. Of searching for the Stone, or passing a Catheter into the Bladder for drawing off Urine in case of a Retention.

471

THE patient being laid on a horizontal table, with his thighs elevated and a little extended, pass the sound with the concave part towards you, until it meets with some resistance in *perineo*, a little above the anus: then turning it without much force, push it gently on into the bladder; and if it meets with an obstruction at the neck, raise its extremity upwards, by inclining the handle of it towards you; or if it do not then slip in, withdraw it a quarter of an inch, and, introducing your fore-finger into the rectum, lift it up, and it will seldom

Præfice. seldom fail to enter. There is some art in turning the found in the proper place of the urethra, which furgeons not verfed in this operation cannot fo well execute; therefore they may pafs the inftrument with the concave fide always towards the abdomen of the patient, obferving the fame rule at the entrance into the bladder as in the other method. The caufe of this obftacle, befides the rugæ of the urethra, and the refiftance of the verumontanum, is fometimes a fmall projection of the orifice of the bladder in the urethra, like that of the os tincæ in the vagina, which occafions the end of the found to fliip a little beyond it.

SECT. XII. *Of Lithotomy.*

473 **Lithotomy** reckoned exceedingly dangerous by the ancients. THE removal of the ftone from the urinary bladder, by the operation called lithotomy, has been ever claffed amongft the moft dangerous operations in furgery, and, till lately, was attempted but by very few, who were diftinguifhed by the title of *lithotomifts*. And this appears probably to have been the cafe in the time of Hippocrates, if any thing may be concluded from the oath afcribed to him; in which he declares, "He will not cut fuch as have the ftone, but leave that operation to thofe who make it their peculiar practice."

473 **Celfus's method.**

474 **Of the high operation.**

475 **Of the lateral operation.**

476 **Of the new method.**

The moft ancient method of cutting for the ftone with which we are acquainted, is defcribed with great accuracy and elegance by Celfus, who makes an incifion in *perineo* immediately upon the ftone, though not in the fame direction with that which is now made in what is called the *lateral operation*. He fays, "A lunated incifion is to be made near the anus down to the neck of the bladder, fo as the horns of the incifion may point towards the coxæ; and from the bottom of the wound thus made, where it is narrower, a fecond incifion muft be made tranfverfely; by which the neck of the bladder is to be opened, and a paffage made for the urine, and the ftone expofed; and moreover, this wound is to be larger than the fize of the ftone," for reasons which he gives. The operation defcribed by Celfus is, in contradiftinction to a more modern one invented by Johannes de Romanis, in which a greater number of inftruments were employed, called *apparatus minor*.

Petrus Francus, finding a ftone too large to be taken away through an opening in *perineo*, boldly made an incifion through the integuments and mufcles, above the offa pubis, into the bladder, and happily extraded it. This method has fince been revived, and prafticed by fome others, under the title of the *high operation*.

Modern praftitioners have adopted that which is called the *lateral operation*. Frere Jaques was, without doubt, the firft perfon who gave the hint: and though he was extremely ignorant, yet, from the knowledge of the parts concerned in the operation, many eminent furgeons were convinced of the great probability there was of its being made a very excellent method, by correcting his errors; among whom was profeflor Rau in Holland, and Mr Chefelden in England.

Heifter feems to prefer Celfus's method (as he underftands it) in lads under 14 years of age, and chiefly on account of fewer inftruments being employed in this than in other methods.

The new method, or *apparatus magnus*, feems to be projected merely from the obfervation made of the

great dilatability of the cervix veficæ, and parts adjacent, when the ftone is extraded in women. Therefore, as by cutting under the fcrotum, clofe to the raphe on the left fide, in *perineo*, through the integuments and mufcles, as low down as the upper part of the anus, then carrying the knife deeper to divide the urethra, the parts divided by thefe openings are brought nearly into the ftate of the urethra in women, thofe who perform this operation muft depend on the dilatation of the parts in one as well as the other for the paffage of the ftone, when it is extraded by this method.

When it is determined that the operation fhall be performed, the manner of preparing the patient depends on various circumftances. For example, if he is plethoric, a few ounces of blood fhould be taken away; and, at proper diftances of time, the bowels muft be emptied; the patient's diet fhould be chiefly milk and vegetables, or other light food; which regimen fhould be obferved for fome days before the operation. The opening medicines fhould be principally manna, or fuch other lenients as will beft answer the purpofe: if the pain fhould be violent, bleeding becomes as neceffary fometimes as in plethorics; but opium muft be employed to abate the excefs of pain: neverthelefs it may be advifable to try firft the effect of keeping the patient on the bed with his hips raifed, in order, if poffible, to roll the ftone from the neck of the bladder: he fhould not, on any account, be permitted to fit up or ufe motion during the preparation for this operation.

It has been frequently remarked, on a diaphoresis coming on after operations in general, that the pain abated, and other difagreeable fymptoms went off. "This (fays Mr Bromfield), induced me to make **477** Mr Bromfield's method of operating. ufe of the warm bath at proper diftances of time, according to the ftrength of the patients, as a part of the preparatory plan for this operation, and it always fucceeded to my utmoft expectations: for from the fkin being well cleaned and foftened by the warm water, an anodyne feldom failed to produce a gentle perfpiration after the operation was performed, and generally prevented the ufual fymptomatic fever confequent to operations.

"If the patient is an adult, the perineum fhould be fhaved and well cleaned. An hour or two before the operation is to be performed, a clyfter fhould be given to empty the rectum; and a few minutes before he is to be cut, he fhould make as much water as he can.

"The patient being laid on a table covered with blankets, pillows, &c. and properly fecured by ligatures and affiftants, I pafs the ftaff into the bladder, and incline the handle towards the abdomen, and obliquely to the right groin, fo as to feel the groove of the ftaff in the perineum on the left fide of the raphe, which will be in the membranous part of the urethra. I then fix it, and deliver it to my affiftant, and defire him to prefs it gently in order to advance the fulcus of the ftaff in the direction in which I had given it to him; another affiftant fupports the fcrotum. I then feat myfelf on a chair of a convenient height, and begin my incifion of the external integuments about half an inch below the commiffure of the offa pubis on the left fide of the raphe, and purfue it by a quick ftroke, obliquely

obliquely outwards and downwards, between the anus and obtuse process of the ischium, ending somewhat lower than the basis of that process. As soon as the integuments are thus divided, I introduce the fore and middle fingers of my left hand; with the last I keep back the lip of the wound next the raphe, and with the index press down the rectum. I then make a second incision, almost in the same direction with the first, but rather nearer to the raphe and anus, and sufficiently deep to divide the transversalis penis, and as much of the levator ani and ligamentous membrane as will make the prostate gland perceptible by my finger. I then with the index of my left-hand feel for the sulcus of the staff, which serves as a conductor to my knife for opening the membranous part of the urethra, and afterwards for dividing part of the prostate: the rectum is likewise by my fingers kept out of the way of the knife in the next part of the operation, which I effect in the following manner. Hitherto I held the blade of my knife like a pen, between the fore-finger and thumb, and resting on the middle finger of my right-hand, with the back of the blade uppermost; but now I take it between the fore-finger and thumb of my right, with the handle towards the palm of my hand on the inside, the back of the blade facing the inside of the index of the right hand: I then turn the back of this hand that holds the knife downwards, and convey the knife to the membranous part of the urethra, by gliding the under fingers of my right-hand on the index of my left-hand, which serves as a conductor of the knife to the gland. As soon as I perceive that, I feel for the groove of the staff with the index of my left-hand, with which I convey the convex edge of the knife into the membranous part of the urethra, as much laterally as is possible, and as nigh to the prostate. When I am clearly in the sulcus of the staff, I turn the back of my knife as much downwards as I can to avoid wounding the rectum, as I then push the blade of the knife along the groove of the staff into the body of the gland, sliding the knife on the convexity of its edge, till it has divided near half the length of that gland; and if I wish to cut a little more of it, I incline the handle of my knife a little downwards, and towards the left ischium. The point of the knife will then drop into the groove of the staff; and by drawing the knife in this situation towards me, I shall certainly make good the wound of the prostate, so as near two-thirds of it may be divided in the operation. This last stroke of my knife is what is generally called *cutting from within outwards*. I then introduce the beak of the common gorgeret into the groove of the staff, and press it on till it gets into the bladder, which is soon discovered by the flux of the urine. I order my assistant to withdraw the found, and I then turn the convex part of the gorgeret towards the wound made in the prostate, and glide the fore-finger of my left-hand in the concave part of the gorgeret till it enters the bladder: by this means I easily and gradually dilate the neck of the bladder; which being done sufficiently, I withdraw my finger, and introduce the forceps. If I do not readily feel the stone with my forceps shut, I give a gentle stroke with them on the part of the bladder near its neck, which is in contact with the rectum; by which means the stone will often

drop down: if not, I rest one cheek of the forceps on the part I had before given the stroke, and, by raising the other, open the forceps: the inferior blade then becomes the axis, on which I turn the upper branch, first to one side, and then to the other, making them gradually approach each other; by which means I generally can lay hold on the stone. When I attempt to extract it, I do it very gently, till I find resistance from the adjacent parts. I then endeavour to prevent the forceps from pressing too much on the stone, by placing the thumb of my left hand as near the joint of the forceps as I can, which, unless the stone is very soft, will prevent its breaking. If any vessel of consequence should be wounded, I take it up by the needle and ligature or tenaculum; if small, I only apply a piece of dry lint to the mouth of the bleeding vessel.

"In case the bladder has not been duly emptied before the operation, great care should be taken in extracting the stone, especially if small; for there not being time for the bladder to contract itself duly, it naturally will fall into wrinkles; these will be liable to be laid hold on together with the stone, which might prove fatal. If the stone is very large, I make use of a screw I have contrived, which may be passed through a hole in one of the branches of the forceps, in which is a female screw: by turning the male screw, you may determine to the greatest exactness the degree of pressure you would choose to make to secure the stone in the forceps.

"Though I have given this rule to prevent the breaking of a stone, yet I think the hazard is greater, in respect to the patient's life, where the stone is large and hard and the incision small, if it should not break, than if it should by the resistance of parts undivided. But still in this case there is danger from some fragments remaining behind (which will probably become nuclei for the formation of other stones), as well as from the forceps being so frequently introduced as may be necessary to their extraction. But I think that when the stone is very large, the best way will be, to bring it forward with your forceps, then secure them by your screw from making too great compression: you may then make your incision on the stone laterally through the prostate gland; which is certainly preferable to risking the laceration and confusion of the parts, by extracting so large a body through an opening naturally so small. I highly disapprove of turning the stone from one side to the other when in the forceps, by way of dilating the neck of the bladder; as the points of the stone, particularly if it should prove of the mulberry form, will probably lacerate the parts, and occasion large sloughs, and frequently cause a mortification. Andreas a Cruce is so apprehensive of the ill consequences of extracting a large stone through the neck of the bladder, that he has contrived forceps with large teeth in order to break the stone to pieces: he has likewise recommended a sort of scoop or spoon in order to take out the broken pieces, as he seems extremely sensible of the ill consequences attending the smallest pieces being left in the bladder. To inform himself whether the bladder be totally free from any fragments of the stone, he has contrived an instrument he calls *verriculum*, with which he examines carefully every part of the bladder: he

says,

Practice.

says, that the most eminent operators of his time neither used dilators nor instruments to break the stone, but trusted to their fingers or the goose-bill forceps for the extraction. Should any small branches of the pudica interna be wounded in the operation, in case a large stone has been extracted, the bleeding will rather be of service than prejudicial; and I should rather encourage it, by fomenting the wound and parts adjacent with some emollient fucus, in which there is a third or fourth part vinegar. A pledget of soft digestive is to be laid on the surface of the wound, which should be frequently renewed: for the dressing being pressed down deep in the wound, with a view to obtain granulations from the bottom, is extremely likely to make the wound fistulous; which seldom happens by the superficial method of dressing. Excoriations of the buttocks may be prevented by placing a sheet under them several times doubled, so as to be in breadth about 18 or 20 inches: it must be rolled up all but as much as is necessary to be laid under the patient. At first the remainder of the roll is put by his side, which unrolls as the nurse draws the wet part from under him: by this method he is almost constantly kept dry. If excoriations should happen, or any other unfavourable symptom, surgery will direct what should be done. I generally keep the patient on a low diet for a week or ten days, as occasion may require.

"To obtain the first stool, a clyster for the most part is necessary; which I greatly prefer to purging medicines given by the mouth, as they frequently occasion more stools than one would wish. I think I have sometimes gained time, after the urine had passed a day or two by the usual channel, by applying compresses and slips of plaster on the lips of the wound to keep them in contact, assisted by the T bandage.

"Having frequently observed in several of my pupils, when they attempted to perform this operation on dead subjects, that they had great difficulty in getting at the prostate gland, so as to divide it properly; and having repeatedly remarked the embarrassment that several operators have had in effecting it on the living subject; I was induced, many years since, to show, in my courses of operations, the two following instruments: the first by the French is called *bistourie cachée*; the method of using which is as follows.

"The incision of the external integuments being made as above directed, the membranous part of the urethra is then to be opened with the point of the knife laterally, as near to the prostate gland as possible: through this opening of the urethra, the bistourie cachée is to be introduced by the groove of the staff into the bladder; as soon as that is effected, the instrument should be disengaged from the staff, which may then be withdrawn. You then place the instrument in such direction, as, when you withdraw, it to make the wound of the gland on the left side, rather obliquely downwards and outwards than horizontally lateral. When you have placed your instrument to your mind, incline the handle towards your patient's left thigh; then press on the spring, which will bring out the blade of the knife that before was concealed in the groove, and withdraw it, observing that obliquity of the handle towards the left thigh during the whole time you are dividing the neck of the bladder. There is great

nicety in making this drawing cut: for if the blade of the knife be not placed with some obliquity downwards, it will wound the ereclor penis, and that branch of the hypogastric artery called *pudica externa*; if placed quite perpendicular, it will wound the vesiculæ feminales and intestine. If you withdraw it in a straight line towards you, the bladder will be wounded beyond its neck. These hints observed, the instrument I think will be of use to those who find a difficulty in dividing the gland with a knife.

"The other instrument I call the *double gorgeret*. The upper part on which the blade is fixed must be united with the under half, by means of the grooves in its upper edges receiving the lower edges of that part with the knife affixed; they then become one instrument, which, if the blade is taken off, somewhat resembles the extreme part of a cow's horn. The manner of using this instrument is as follows: The incisions of the integuments and urethra being made as directed for cutting with the bistourie cachée, the beak of the gorgeret is to be introduced into the groove of the staff. I then take the staff from my assistant with my left-hand, and incline the handle to the patient's left groin; in which situation, I can pass the instrument with the blade pointing obliquely outwards and downwards, and then push it on quite into the bladder, of which I am informed by the urine running through the instrument, which serves as a direction how much farther the instrument should be pushed on, in order to divide about two-thirds of the length of the gland. I then withdraw the upper half of the instrument with the blade, the lower part that remains becoming the common gorgeret. I should have remarked, that I take the instrument, when its parts are united, in my right hand, the wooden handle resting in the palm against the ball of my thumb, and my thumb placed on the upper part of the handle: by this means the two parts of the instrument will be kept in contact when used, merely from the resistance of the prostate gland, &c. during its introduction. The remaining part of the operation is finished as usual in the lateral method; except that when you want to disengage the forceps, it will be necessary to raise the left-hand that holds the gorgeret, at the same time that the right is depressed. It is possible I may be of the partial to my own contrivance; but I cannot say that I have ever seen any other instrument that has been since made, formed with the same intentions with mine. The common gorgeret, if it does not cut on its edge, and the membranous part of the urethra only be opened, will probably force off the prostate gland and neck of the bladder from its continuation with the urethra; which Mr. Cheselden assured me has more than once been the case, from the shoulders near the beak not being able to dilate, unless the prostate is in some measure divided at its connection with the membranous part of the urethra: therefore I find the double gorgeret, even without the blade, is more easily introduced than the common gorgeret, and without hazard, as by dilatation it prepares the parts for the introduction of the forceps; which preparatory dilatation is still of greater service when the gland is to be divided with the blade affixed; and the lower part of the gorgeret will defend the intestine and vesiculæ feminales from being wounded.

Practice.

478
Instruments used by Mr. Bromfield in performing the operation.

479
Advantages of the double gorgeret.

"Many who espouse the lateral operation, as it is called, conclude, that the gland should be wounded laterally and horizontally; and for that purpose have invented various instruments to cut it through its whole length, to facilitate the extraction of a large stone. The prostate gland, I believe, is very rarely entirely divided in the present method of performing the operation, and I think never horizontally laterally, as is supposed; which indeed is obvious from the situation of the groove of the staff, which must cause the opening to be in the under part of the gland, a little to the left side. When the common dissecting knife only is employed, some, as soon as they have made an opening into the urethra, in that part where the groove of the staff can be felt most sensibly, in order to avoid wounding the rectum, divide the gland obliquely upwards and outwards. From what I have seen of this method of operating, I am convinced there is not any advantage in it; but, on the contrary, that it is rather prejudicial where the stone is large: for the resistance of the gland being taken away in the upper part by the incision, and the ligamentous and muscular parts remaining undivided below, the stone is thrown up towards the symphysis of the bones of the pubis, which is the smallest part of the angle of the pelvis, through which the stone is to pass: the great force consequently requisite to extract it, under these circumstances, frequently occasions the stone to be broken, and the neighbouring parts very much contused and lacerated; which could not be the case, were all the resistance taken away below where the distance between the ischia is greatest.

"Though almost all operators would gladly wish (by what I understand) to divide the prostate gland throughout its whole length, it is what I would always choose to avoid: about two-thirds of it nearest to the membranous part of the urethra, I am convinced, will be sufficient, and attended with more advantages than the cutting it entirely through; as the only obstacle a stone meets with is in that part of the gland, and as the neck of the bladder beyond that will dilate sufficiently in most cases without laceration, and as the wounded parts will sooner heal by the muscular fibres, which act as a sphincter, recovering their tone, than they would do if the urine were constantly running through them. By this method of operating, and proper treatment of the wound afterwards, I do not recollect a single instance of a fistula remaining."

SECT. XIII. Of Castration, and the Extirpation of Encysted and Cancerous Tumours.

§ 1. Of Castration.

This is one of the most melancholy operations in the practice of surgery, since it seldom takes place but in disorders into which the patient is very apt to relapse, viz. those of a scirrhus or cancer: for under most of the symptoms described as rendering it necessary, it is absolutely improper; such as a hydrocele, abscess of the testes, an increasing mortification, or what is sometimes understood by a sarcocele; of which last it may not be amiss to say a word. In the utmost latitude of the meaning of this term, it is received as a fleshy swelling of the testicle itself, called likewise *hernia carnea*; or in some enlargements, such

as in a clap, more frequently *hernia humoralis*; but generally speaking, is considered as a fleshy excrescence formed on the body of the testis, which becoming exceedingly hard and tumefied, for the most part is supposed to demand extirpation, either by cutting or burning away the induration, or amputating the testicle. But this maxim too precipitately received, has very much misguided the practitioners of surgery.

It sometimes happens that the epididymis is tumefied, independent of the testicle; and, feeling like a large adventitious excrescence, answers very well to the idea most surgeons form of a *sarcocele*: but not being aware of the different nature and texture of the epididymis, they have frequently confounded its disorders with those of the testicle itself, and equally recommended extirpation in the induration of one and the other. But all indurations of the glandular part of the testicle not tending to inflammation and abscess, generally, if not always, lead on to scirrhus and cancers; whereas those of the epididymis seldom or never do. It is true, in spite of internal or external means, these last often retain their hardness, and sometimes suppurate, but, however, without much danger in either case.

Before castration, it is laid down as a rule to inquire whether the patient has any pain in his back; and in operation that case to reject the operation, upon the reasonable presumption of the spermatic vessels being likewise diseased: but we are not to be too hasty in this determination; for the mere weight of the tumour stretching the cord, will sometimes create this complaint. To learn the cause, then, of this pain in the back, when the spermatic cord is not thickened, let your patient be kept in bed, and suspend his scrotum in a bag-truss, which will relieve him, if disordered, by the weight only; but if the spermatic cord is thickened or indurated, which disease, when attended with a dilatation of the vessels of the scrotum, is known by the Greek appellations *circocoele* and *varicocoele*, the case is desperate, and not to be undertaken.

But supposing no obstacle in the way to the operation, the method of doing it may be this. Lay your patient on a square-table of about three feet four inches high, letting his legs hang down, which, as well as the rest of his body, must be held firm by the assistants. Then with a knife begin your wound above the rings of the abdominal muscles, that you may have room afterwards to tie the vessels, since for want of this caution operators will necessarily be embarrassed in making the ligature: then carrying it through the *membrana adiposa*, it must be continued downward, the length of it being in proportion to the size of the testicle. If it is very small, it may be dissected away without taking any part of the scrotum. If the testicle, for instance, weighs twenty ounces; having made one incision about five inches long, a little circularly, begin a second in the same point as the first, bringing it with an opposite sweep to meet the other in the inferior part, in such a manner as to cut out the shape of an oval whose smallest diameter shall be two inches: after this dissect away the body of the tumour, with the piece of skin on it, from the scrotum; first taking up some of the blood-vessels, if the hæmorrhagy is dangerous. Then pass a ligature round the cord, pretty near the abdomen; and, if you have space between

tween the ligature and testicle, a second about half an inch lower, to make the stoppage of blood still more secure. The ligatures may be tied with what is called the *surgeon's knot*, where the thread is passed through the ring twice. This done, cut off the testicle a little underneath the second ligature, and pass a needle from the skin at the lower part of the wound thro' the skin at the upper part, in such a manner as to envelope in some degree the found testicle, which will greatly facilitate and quicken the cure; or if one stitch will not answer the purpose, you may repeat it in such part of the wound where the skin on each side lies most loose.

In large tumours, it is advisable to cut away great part of the skin; for besides that the hæmorrhagy will be much less in this case, and the operation greatly shortened, the skin by the great distention having been rendered very thin, will great part of it, if not taken away, sphacelate, and the rest be more prone to degenerate into a cancerous ulcer.

§ 2. Of Encysted Tumours.

That called *scatoma** is never painful until by its weight it grows troublesome, nor is it a mark of general indisposition of body; so that the extirpation seldom fails of success. The size of some of them is very large, frequently weighing five or six pounds, and there have been instances of their weighing above forty.

When the *scatoma* is irregular in its surface, with eminences and depressions, it is fleshy; whereas the fat one has for the most part a uniform smooth outside. The operation for the *scatoma* will be understood by the description of that for the scirrhus.

The *anthierama*† is much more common than the *meliceris*‡; at least, if all encysted tumours with matter not curdled, may, in compliance with custom, be called so: These are more frequent, and grow larger than those where the matter is curdled, being often attendant on scrophulous indispositions, which makes them more difficult of cure.

The cysts of these tumours, with the skin covering them, after a certain period of growth, resisting any further enlargement, do frequently inflame and break; but this opening is not so advantageous for the cure as extirpation by the knife, which should be done in the infancy of the swelling. When the tumours are no bigger than a small golden pippen, they may be dissected away from under the skin, by making a straight incision only through it; but if they exceed this bulk, an oval piece of skin must be cut through first, to make room for the management of the knife and taking away the tumour; in which case, it will be advisable to take off the upper portion of the cyst with the skin; and then, by the help of a hook, to dissect away as much of the remainder of it as can be conveniently, which is a less painful and more secure method than destroying it afterwards with escharotics. This rule is to be observed when the cyst runs so deep amongst the interstices of the muscles, as to make it impossible to remove the whole of it, where, if we cut off a great quantity, the rest usually comes away in sloughs and matter.

The *ganglion* of the tendon is an encysted tumour of the meliceris kind, but its fluid is generally like the white of an egg: when it is small, it sometimes dissolves of itself; pressure and sudden blows do also re-

move it; but for the most part it continues, unless it be extirpated. It is no uncommon case to meet with this species of ganglion running under the ligamentum carpalæ, and extending itself both up the wrist and down to the palm of the hand. The cure of this disorder cannot be effected but by an incision through its whole length and dividing the ligamentum carpalæ.

The dressing in these cases does not at all differ from the general methods of treating wounds.

§ 3. Of the Amputation of the Cancered and Scirrhus Breast.

When a scirrhus has admitted of a long delay before the operation, the patient seems to have a better prospect of cure without danger of a relapse, than when it has increased very fast, and with acute pain.

The scirrhus may be distinguished, by its want of inflammation in the skin, its smoothness and slipperiness deep in the breast, and generally by its pricking pain; which as it is more or less, increases the danger accordingly; though there are some few with little or none in the beginning: as the tumour degenerates into a cancer, which is the worst degree of scirrhus, it becomes unequal and livid, and the vessels growing varicose, at last ulcerates.

In extirpating the scirrhus, if it be small, a longitudinal incision will dilate sufficiently for the operation; but if too large to be dissected out in that manner, an oval piece of skin must be cut through first, the size of which is to be proportioned to that of the tumour; for example, if the swelling is five inches long and three broad, the oval piece of skin cut away must be nearly of the same length, and about an inch and a half in breadth. In taking off the whole breast, the skin may be very much preserved, by making the wound of it a great deal less than the basis of the breast, which must be carefully cleared away from the pectoral muscle. This is not difficult to do, because all these scirrhuses being enlarged glands, are encompassed with their proper membranes, which make them quite distinct from the neighbouring parts, and easily separable: at least this is the case when the tumour is moveable; for sometimes it adheres to the subjacent muscle, and that muscle to the ribs; in which circumstance, the operation is impracticable. When it is attended with knots in the arm-pit, no service can be done by amputation, unless the knots be taken away; for there is no sort of dependence to be laid on their subsiding, by the discharge of the wound of the breast.

The bleeding of the large arteries is to be stopped by passing the needle twice through the flesh, almost round every vessel, and tying upon it, which will necessarily include it in the ligature. In order to discover the orifices of the vessels, the wound must be cleaned with a sponge wrung out of warm water.

The scirrhus tumours which appear about the lower jaw, are, generally speaking, scrophulous disorders, that distinguish themselves almost by the circumstance of fixing on the salivary glands. These are very stubborn of cure, but not so bad as the scirrhus, since they frequently suppurate, and heal afterwards: if they impolthumate again after healing, it is for want of a good bottom, which may sometimes be procured by destroying their bad surface with a caustic. Besides these, there is another species of scirrhus in the neck,

that succeeds better after extirpation than either of the former kind; this is an enlargement of the lymphatic glands, which run close up by the jugular vein, and is distinguishable from the cancers of this part, by its moveableness, want of pain, the laxness of the skin covering it, the small degree of pressure it makes on the oesophagus and trochea, and lastly the good habit of body, as it seldom affects the constitution, which cancers here do very early, after their first appearance. This tumour, from its situation, requires great exactness in the cutting off: they sometimes extend up to the chin towards the mouth, and occasion a division of the salivary duct in operating, which proves very troublesome to heal; but, when all other methods have failed, may be cured by a perforation into the mouth, through that part of the cheek where it is wounded, which by a tent or small seton may be made fistulous; then, by properly dressing upon the outside, the oozing of the saliva that way will be prevented, and the external orifice healed without difficulty.

The treatment of all these wounds may be with dry lint first, and afterwards as in common wounds.

SECT. XIV. *Of the Operation for the Empyema, Ascites, and Hydrocele.*

§ 1. *Of the Empyema.*

The operation for the empyema implies an artificial opening made into the cavity of the thorax, by which we evacuate any fluid that lies there extravasated, and is become dangerous by its weight and quantity. The fluids described as necessary to be avoided by this operation, are blood, matter, and water.

485
Of the different cases in which the operation for empyema is requisite.

When blood is the fluid supposed to require evacuation by this method, it is always extravasated through some wound of the vessels of the lungs or thorax; and being discharged in great quantities on the diaphragm, is said to oppress respiration, till let out by some convenient opening made in the most depending part of that cavity, which is the only kind of perforation into the thorax distinguished by the name of the operation for the empyema: But though this opening is universally recommended in the case here stated, yet we meet with few or no examples where it has been practised for a mere extravasation of blood.

The second circumstance in which this operation takes place, is a rupture of matter from the pleura, mediastinum, or lungs, into the cavity of the thorax; where accumulating, it at length proves fatal for want of a discharge. It is true, that the case occurs but very seldom where the operation is necessary; because, in most abscesses of the thorax, the matter is usually spit up as fast as it is generated; and in the dissection of those who have died of this species of consumption, we rarely find much extravasated pus in the cavity, though a great portion of the lungs be destroyed. However, there are a few cases which require the operation; and these may be distinguished by the following symptoms. The patient is obliged to lie upon the diseased side, or, in case there is matter in both cavities of the thorax, on his back; because the mediastinum can seldom support the weight of the incumbent fluid, without suffering great pain. But this rule is not certain, it sometimes happening that the patient can lie with ease on that side where

there is no fluid. Another symptom of extravasated matter, is an evident undulation of it, so that in certain motions it may be hard to quash. For the most part too, upon careful inquiry, an œdema, or at least a thickening of some portion of the intercostal muscles, will be discovered. And lastly, if there be much fluid, it will be attended with a preternatural expansion of that side of the chest where it lies. When therefore these signs appear after a previous pleuritic or pulmonary disorder, and the case has been attended with the symptoms of a suppuration, it is most probably owing to a collection of matter; though, the patient will also labour under a continual low fever, and a particular anxiety from the load of fluid.

The last sort of fluid said to require issue from this operation is water, which however very seldom collects in such manner as to become the proper subject of the operation: for if the dropsy of the thorax be complicated with an anasarca, or even ascites, it is certainly improper; and indeed it hardly ever takes place, but where the distemper is single, and takes its rise from the same sort of disorders in the lymphatics of the pleura, as the hydrocele does from those of the tunica vaginalis. The symptoms of this dropsy are, a small cough without spitting; a little slow fever, from the disturbance of respiration; sometimes, too, the water, by a sudden jerk, may be heard to quash; and generally speaking, its weight upon the diaphragm and mediastinum are so troublesome as to oblige the patient to stoop forward, and to turn upon the affected side when he lies down; for the same reason, when there is water in both cavities of the thorax, he is forced to lie on his back.

The manner of operating, whether it be for the discharge of matter or water, is to pitch upon the depending part of the thorax, which some have supposed to be between the eighth and ninth ribs, and others between the ninth and tenth, at such a distance from the vertebræ that the depth of the flesh may not be an impediment to the perforation. This distance is determined to be about a hand's-breadth: and here, with a knife, scissars, or trocar, we are ordered to make the perforation; but in doing it there are a great many difficulties. In fat persons, it is not easy to count the ribs, and the wound will be very deep, and troublesome to make; it is hardly possible to escape wounding the intercostal artery, which runs in this place between the ribs. But if the only advantage proposed by the situation of the wound be derived from its dependency, the purpose of discharging the fluid will be as well answered by an opening between the sixth and seventh ribs, half way from the sternum towards the spine; which, by laying ourselves down, becomes in effect as depending an orifice as the other in sitting up; and by an opening made in this manner we avoid all the inconveniences in the other method: for in this part of the thorax there is very little depth of muscles; the artery lies concealed under the rib; and the diaphragm is at a great distance. The opening is best made with a knife; and should be about an inch long through the skin, and half an inch through the subjacent muscles: tho', to make the incision with less risk of wounding the lungs, it may be advisable to dilate it with the blunt-pointed knife (as is practised in the operation for the bu-

486
Method of performing

Practice. bubonocoele), after having made a small puncture with a common knife. The treatment of the wound will be according to the nature of the discharge. If, after a few days, there appears no drain, you may let the orifice heal up; but if it continues, it may be kept open with a short silver canula, until such time as an alteration in that circumstance will give us leave to cicatrize with safety.

§ 2. *Of the Paracentesis, or tapping for the Dropsy.*

THIS operation is an opening made into the abdomen, in order to empty any quantity of extravasated water, collected in that species of dropsy called the *ascites*; but as there is much more difficulty in learning when to perform than how to perform it, and indeed in some instances requires the nicest judgment, we shall endeavour to specify the distinctions which render the undertaking more or less proper.

⁴⁸⁷ There are but two kinds of dropsy: the anasarca, called also *leucophlegmacy*, when the extravasated water swims in the cells of the *membrana adiposa*; and the *ascites*, when the water possesses the cavity of the abdomen. In the first kind, the water is clear and limpid; but in the second, a little grosser, very often gelatinous and corrupted, and sometimes even mixed with fleshy concretions.

The operation of tapping is seldom the cure of the distemper: but dropsies, which are the consequence of a mere impoverishment of the blood, are less likely to return than those which are owing to any previous disorder of the liver; and it is not uncommon for dropsies that follow agues, hæmorrhages, and diarrhoeas, to do well; whereas in such as are complicated with a scirrhus liver, there is hardly an example of a cure.

The water floating in the belly, is, by its fluctuation, to determine whether the operation be advisable; for if, by the laying one hand on any part of the abdomen, you cannot feel an undulation from striking on an opposite part with the other, it is to be presumed there will be some obstacle to the evacuation. It sometimes happens, that a great quantity, or almost all the water, is contained in little bladders, adhering to the liver and the surface of the peritonæum known by the name of *hydatids*; and the rest of it in different-sized ones, from the degree of a hydatid, to the size of a globe holding half a pint or pint of water. This is called the *encysted dropsy*, and from the smallness of its cysts makes the operation useless; but is not difficult to be distinguished, because there is not a fluctuation of the water, unless it is complicated with an extravasation.

When the fluctuation is hardly perceptible, (except the teguments of the abdomen are very much thickened by an anasarca), in all probability the fluid is gelatinous.

There is another kind of dropsy, which for the most part forbids the operation, and is peculiar to women, being seated in the body of one or both ovaries. There is no example of this species but what may be known by the hardness and irregularity of the tumour of the abdomen, which is nearly uniform in the other cases.

When the ovary is dropical, the water is generally deposited in a great number of cells formed in the body of it; which circumstance makes the fluctuation

insensible, and the perforation useless: though sometimes there are only one or two cells; in which case, if the ovary is greatly magnified, the undulation will be readily felt, and the operation be advisable.

When the ascites and anasarca are complicated, it is seldom proper to perform the operation, since the water may be much more effectually evacuated by scarifications in the legs than by tapping.

Upon the supposition that nothing forbids the ex-⁴⁸⁸traction of the water, the manner of operating is this. *tapping.*

Having placed the patient in a chair of a convenient height, let him join his hands so as to press upon his stomach; then dipping the trocar in oil, you stab it suddenly through the teguments, and, withdrawing the perforator, leave the waters to empty by the canula. The abdomen being, when filled, in the circumstance of a bladder distended with a fluid, would make it indifferent where to wound; but the apprehension of hurting the liver, if it be much enlarged, has induced operators rather to choose the left side, and generally in that part which is about three inches obliquely below the navel. If the navel protuberates, you may make a small puncture with a lancet through the skin, and the waters will be readily voided by that orifice, without any danger of a hernia succeeding; but it should be carefully attended to whether the protuberance is formed by the water or rupture; in which latter case, the intestine would be wounded, and not without the greatest danger. The surgeon, neither in opening with the lancet, nor perforating with the trocar, need fear injuring the intestines, unless there is but little water in the abdomen, since they are too much confined by the mesentery to come within reach of danger from these instruments; but it sometimes happens, that when the water is almost all emptied, it is suddenly stopped by the intestine or omentum pressing against the end of the canula; in which case you may push them away with a probe. During the evacuation, your assistants must keep pressing on each side of the abdomen, with a force equal to that of the waters before contained there: for, by neglecting this rule, the patient will be apt to fall into faintings, from the weight on the great vessels of the abdomen being taken off, and the sinking of the diaphragm succeeding; in consequence of which, more blood flowing into the inferior vessels than usual, leaves the superior ones of a sudden too empty, and thus interrupts the regular progress of the circulation. To obviate this inconvenience, the compression must not only be made with the hands during the operation; but be afterwards continued, by swathing the abdomen with a roller of flannel, about eight yards long and five inches broad, beginning at the bottom of the belly, so that the intestines may be borne up against the diaphragm: you may change the roller every day till the third or fourth day, by which time the several parts will have acquired their due tone. For the dressing, a piece of dry lint and plaster suffice; but between the skin and roller it may be proper to lay a double flannel a foot square, dipt in brandy or spirit of wine.

This operation, though it does not often absolutely cure, yet it sometimes preserves life a great many years, and even a comfortable one, especially if the waters have been long collected.

§ 3. Of the Hydrocele.

Practice.

THE term *hydrocele*, if used in a literal sense, means any tumour produced by water; but surgeons have always confined it to those which possess either the membranes of the scrotum, or the coats of the testicle and its vessels.

The first of these, viz. that which has its seat in the membranes of the scrotum, is common to the whole bag, and to all the cellular substance which loosely envelopes both the testes. It is, strictly speaking, only a symptom of a disease, in which the whole habit is most frequently more or less concerned, and very seldom affects this part only. The latter, or those which occupy the coats immediately investing the testicle and its vessels, are absolutely local, very seldom affect the common membrane of the scrotum, generally attack one side only, and are frequently found in persons who are perfectly free from all other complaints.

439
Different kinds of hydrocele confounded together by chirurgical writers.

Notwithstanding the obvious and material difference between the two kinds of disease, they have by the majority of writers been confounded together; have been considered as springing from the same immediate source, and as requiring the same kind of treatment; although the one is plainly and evidently a mere symptom or attendant on a general disorder, and the others are strictly and absolutely local complaints. This one fundamental error has been the occasion of many others. The supposition, that all collections found in the membranes and coats of the scrotum and testicles are of the same general kind, has produced an infinite variety of wild conjectures concerning the particular and immediate nature and origin of them. By some they have been attributed to a particular indispotion of the liver, kidneys, or spleen; by others, to a natural and necessary connection between the spermatic vessels and those of the kidney: by many the fluid has been thought to be of the urinary kind, or at least that it ought to have passed through the kidney; but that, mistaking its right way, it gets into the membranes of the scrotum and testicles: while others have affirmed, that all complaints of this kind are really symptoms of a dropsical habit; that the fluid comes from the cavity of the belly, and either passes through the peritoneum, or extends that membrane down into the scrotum. Many cautions have been laid down against attempting the cure of one species of this disease hastily, or without a previous course of medicine, upon a supposition that the defluxion is of a noxious nature, and that by falling on this part it frees the constitution from several other dilempers. It has been described as frequently producing a corrupted or otherwise diseased testicle; as being nearly allied in nature to those tumours which are called encysted, whose tunics are formed out of the common membrane by mere pressure; and as being generally accompanied with a true hernia, or descent of the intestine or omentum; which last (supposed) circumstance has been gravely urged as a reason for not attempting a radical cure. The same wanton liberty has been taken in assigning different seats to these disorders, as in accounting for their origin: every part which invests or accompanies the spermatic vessels or the testicles, not only the tunica communis of the process, and the cavity of the

tunica vaginalis (the true and real seats of one or other of these disorders), have been enumerated, but several imaginary ones have been added; firm compact membranes have been split into lamellæ, and cysts and coats have been devised which never had a real existence.

If all this were matter of mere speculation, and produced no mischief in practice, it would be of no importance; but in matters of physic and surgery this seldom or never happens: erroneous ideas of the nature, origin, and seats of diseases, most commonly are followed by improper methods of treating them. In the present case, the absurdity of the conjectures concerning these circumstances in the disorder, is fully equalled by the methods of cure which have been proposed and practised.

Upon a supposition that the extravasation of fluid was the consequence of a dropsical habit, strong purges and powerfully diuretic medicines have been prescribed; actual cauteries have been used, and ligatures and incisions made, both on the spermatic vessels and in the groin, to hinder the descent of the water from the cavity of the belly; astringent liquors and ardent spirits have been injected, with a view to closing or folding broken lymphatics; tedious and painful operations have been practised for the eradication of imaginary cysts; directions have been given to evacuate the water at different times, lest the patient's strength should fail or his health suffer, by its being done too suddenly; and the testicles being supposed to be frequently spoiled by long lying in the water, castration has often been performed in the simple hydrocele.

The scrotum is the common receptacle of both the testicles, and consists of the cuticula, cutis, and what all the anatomists have now agreed to call the *dartos*; which is a loose cellular membrane, perfectly void of fat, and whose cells or cavities communicate with each other, with the utmost freedom through every part.

As this membrane has no immediate communication with the cavity of the abdomen within the peritoneum, it is plain, that whatever kind or quantity of fluid may be deposited in it, it cannot be derived from the said cavity, even though the patient should labour under a true ascites: but as its cells have a free intercourse with those of the general cellular membrane all over the body, they will be liable to be affected by all those disorders which have their seat in that membrane; that is, by all disorders proceeding from a low impoverished state of blood, from a deficiency of the urinary secretion, or from non-execution of the office of the absorbent vessels; and consequently, in anasarous and leucophlegmatic habits, will become the seat of a watery extravasation.

This watery swelling of the scrotum, although it is most frequently a symptom of a dropsical habit, and very often accompanies both the general anasarca and the particular collection within the abdomen called the *ascites*; yet, even in the latter case, neither is or can be derived from the cavity of belly, but is confined to the tela cellulosa, which lies on the outside of the peritoneum: the water derived from hence distends the scrotum in the same manner, and for the same reasons, that it often does the legs and feet. The cells of the *dartos* being larger and absolutely void of fat, and the skin which covers them being extremely

439
Improper directions for the cure.

Practice.

Practice.

tremely dilatable, and giving way for a larger influx into this part than into most others, has indeed occasioned its being taken notice of as a particular disease, though it is most properly a symptom only.

This being the case, and the true method of cure consisting in an internal medical process, it has been improperly ranked among the species of hydrocele; though the nature of the contents will certainly admit the use of the word.

403
Description
of the wa-
tery swell-
ing of the
scrotum.

It is an equal soft tumour, possessing every part of the cellular membrane in which both the testicles are enveloped, and consequently is generally as large on one side as on the other: it leaves the skin of its natural colour; or, to speak more properly, it does not redden or inflame it: if the quantity of water be not large, nor the distention great, the skin preserves some degree of rugosity, the tumour has a doughy kind of feel, and easily receives and for a while retains the impression of the fingers; the raphe or seam of the scrotum divides the swelling nearly equally; the spermatic process is perfectly free, and of its natural size; and the testicles seem to be in the middle of the loaded membrane. This is the appearance when the disease is in a moderate degree; but if the quantity of extravasated serum be large, or the disease farther advanced, the skin, instead of being wrinkled, is smooth, tense, and plainly shows the limpid state of the fluid underneath: it is cold to the touch, does not so long retain the impression of the finger, and is always accompanied with a similar distention of the skin of the penis; the preputium of which is sometimes so enlarged, and so twisted and distorted, as to make a very disagreeable appearance. These are the local symptoms; to which it may be added, that a yellow countenance, a loss of appetite, a deficiency of urinary secretion, swelled legs, a hard belly, and mucous stools, are its very frequent companions.

The cure of the original disease comes within the province of the physician, and requires a course of internal medicine: but sometimes the loaded scrotum and penis are so troublesome to the patient, and in such danger of mortification, that a reduction of their size becomes absolutely necessary; and at other times a derivation or discharge of the redundant extravasated serum from this part is ordered as an assistant to the internal regimen.

The surgical means in use for this end is called in general *scarification*: a term whose precise sense has by no means been settled; from which it has now and then happened, that a general order being given, and the particular method of executing it being left to the choice of those who have not been sufficiently acquainted with this kind of business, much hazard has been incurred, and considerable mischief done which might have been avoided.

The means of making this discharge are two, viz. puncture and incision: the former is made with the point of a lancet; the latter with the same instrument, or with a knife.

The generality of writers on this subject have spoken of the two methods in such a manner, that a practitioner who had seen but little of either, would be inclined to think that it was a matter of great indifference which we should make use of, and that the

safety and utility of each were equal: which is by no means the case.

The intention of the use of either is, by a discharge of extravasated serum, to alleviate the present uneasiness; and, by reducing the size of the scrotum, to render it less troublesome, and less likely to mortify. In some few instances it has indeed happened, that this drain has proved a radical cure of the original disease; but that has been accidental, and is not in general to be expected. The intention is generally palliative; and, if the patient lives, is most likely to require repetition: therefore, if there be any difference between the two methods, with regard either to ease or safety, there can be no doubt which ought to be preferred.

All wounds of membranous parts in anasarctous or dropsical habits, are necessarily both painful and hazardous; they are apt to inflame, are very difficultly brought to suppuration, and will often prove gangrenous in spite of all endeavours to the contrary. But the larger and deeper the wounds are, the more probable are these bad consequences. Simple punctures with the point of a lancet are much less liable to be attended by them than any other kind of wound; they generally leave the skin easy, soft, cool, uninfamed, and in a state to admit a repetition of the same operation if necessary. Incisions create a painful, crude, hazardous sore, requiring constant care. Punctures seldom produce any uneasiness at all, and stand in need of only a superficial pledget for dressing.

Now although there is so very material a difference in the symptoms and trouble attending the two methods, yet there is none in their effect: the communication of the cells of the dartos with each other is so free through every part of it, that punctures made with the fine point of a bleeding lancet into the most superficial of them, will as certainly and as freely drain off all the water as a large incision, without any of its inconveniences or its hazard.

Another species of hydrocele affects the cells of the tunica communis.

403

nica com-
munis.

When the disease is simple, it is perfectly local; that is, it is confined entirely to the membrane forming the tunica communis, and does not at all affect either the dartos, the tunica vaginalis testis, or any other part.

It is a complaint which does not give a great deal of trouble, unless it arrives to a considerable size; and being by no means so frequent as either of the other two kinds of hydrocele, it is in general but little known or attended to. With some it passes for a varix of the spermatic cord; with others, for the descent of a portion of omentum, which having contracted an adhesion cannot be returned. Thus its true nature not being in general rightly understood, and it giving but little trouble or uneasiness while it is within moderate bounds, and neither hindering any necessary action or faculty, they who have it are most frequently advised to be contented with a suspensory bandage, and find very little inconvenience from it.

Sometimes it arises to so large a size, and gets into such a state, as to become an object of surgery, and to require our very serious attention.

In general, while it is of moderate size, the state of it is as follows. The scrotal bag is free from all appearance

pearance of disease, except that when the skin is not corrugated it seems rather fuller, and hangs rather lower on that side than on the other, and, if suspended lightly on the palm of the hand, feels heavier: the testicle, with its epididymis, is to be felt perfectly distinct below this fulness, neither enlarged, nor in any manner altered from its natural state: the spermatic process is considerably larger than it ought to be; and feels like a varix or like an omental hernia, according to the different size of the tumour: it has a pyramidal kind of form, broader at the bottom than at the top: by gentle and continued pressure, it seems gradually to recede or go up, but drops down again immediately upon removing the pressure, and that as freely in a supine as in an erect posture: it is attended with a very small degree of pain or uneasiness; which uneasiness is not felt in the scrotum where the tumefaction is, but in the loins.

If the extravasation be confined to what is called the *spermatic process*, the opening in the tendon of the abdominal muscle is not at all dilated, and the process passing through it may be very distinctly felt; but if the cellular membrane which invests the spermatic vessels within the abdomen be affected, the tendinous aperture is enlarged, and the increased size of the distended membrane passing through it produces to the touch a sensation not very unlike that of an omental rupture.

While it is small, it is hardly an object of surgery; the pain or inconvenience which it produces being so little, that few people would choose to submit to an operation to get rid of it, and it is very seldom radically curable without one: but when it is large, or affects the membrane within the cavity as well as without, it becomes an apparent deformity, is very inconvenient both from its size and weight, and the only method of cure which it admits is far from being void of hazard; as must appear to every one who will consider, or who is at all acquainted either with the nature of lymphatic extravasation or absorption, or with the frequent consequences of wounds inflicted on parts merely membranous.

The *encysted hydrocele* of the tunica communis has its seat in the same part as the preceding, viz. the tunica communis or cellular membrane, which invests the spermatic vessels; with this difference, that in the former the water is diffused in general through all the cells of the membrane, whereas in this it is contained in one cavity only.

It is a complaint by no means unfrequent, especially in children. It was very well known to many of the ancients, and has been very accurately described by some of them; but later writers have often mistaken it for and represented it as a wind-rupture, or pneumatocele, a disease existing in their imaginations only. It most frequently possesses the middle part of the process, between the testicle and groin, and is generally of an oblong figure; whence it has by some people been compared to an egg, by others to a fish's bladder. Whether it be large or small, it is generally pretty tense, and consequently the fluctuation of the water within it not always immediately or easily perceptible; for which reason it has been supposed to contain air only. It gives no pain, nor (unless it be very large indeed) does it hinder any necessary action. It is

perfectly circumscribed, and has no communication either with the cavity of the belly above, or that of the vaginal coat of the testicle below it. The testis and its epididymis are perfectly and distinctly to be felt below the tumour, and are absolutely independent of it. The upper part of the spermatic process in the groin is most frequently very distinguishable. The swelling does not retain the impression of the fingers; and when lightly struck upon, sounds as if it contained wind only. It undergoes no alteration from change of the patient's posture, nor is affected by his coughing, sneezing, &c. and has no effect on the discharge *per anum*.

Infants are much more subject to this disease than adults, though it often affects the latter. In young children it frequently dissipates in a short time; especially if assisted by warm fomentation, and an open belly. If it does not disperse, that is, if it be not absorbed, the point of a lancet will give discharge to the water, and in young children will most frequently produce a cure. In adults, the cyst formed by the pressure of the fluid does sometimes become so thick as to require division through its whole length; which operation may in general be performed with great ease and perfect safety: though even this may prove troublesome, hazardous, and fatal; of such consequence are wounds in membranous parts in some particular habits.

The third species of this disease is that which is ⁴⁹⁴Hydrocele confined to the vaginal coat or bag which loosely envelopes the testicle. In a natural healthy state, the ⁴⁹⁵Hydrocele cavity of this bag always contains a small quantity of a fine fluid exhaled from the capillary arteries, and constantly absorbed by vessels appointed for that purpose. This fluid in the natural small quantity serves to keep the tunica albuginea moist, and to prevent a cohesion between it and the vaginalis; a consequence which almost necessarily follows any such diseased state of these parts as prevents the due secretion of it. On the contrary, if the quantity deposited be too large, or if the regular absorption of it be by any means prevented, it will be gradually accumulated, and, by distending the containing bag, will form the disease in question.

The two preceding species of hydrocele have their seat in the tunica communis of the spermatic vessels, that is, in the cellular membrane which invests them; one by a general diffusion of lymph through all its cells, the other by a collection of it in one particular cyst or bag: that which makes our present subject has no concern or connection with that membrane at all, but is absolutely confined to the tunica vaginalis testis.

It is a disease from which no time of life is exempt; not only adults are subject to it, but young children are frequently afflicted with it, and infants sometimes born with it.

From all the circumstances attending the complaint, it is pretty clear, that whatever tends to increase the secretion of the fluid into the sacculus beyond the due and necessary quantity, or to prevent its being taken up and carried off by the proper absorbent vessels, must contribute to its production; which is so slow and gradual, and at the same time so void of pain, that the patient seldom attends to it until it has arrived to some size. Not but that it sometimes is produced very sud-

Practice. suddenly, and in a very short space of time attains considerable magnitude.

The size and figure of the tumour are various in different people, and under different circumstances. In general, at its first beginning, it is rather round; but as it increases it frequently assumes a pyriform kind of figure, with its larger extremity downward: sometimes it is hard, and almost incompressible, so much so, that in some few instances it has been mistaken for an induration of the testicle; at other times it is soft and lax, that both the testicle and the fluid surrounding it, are easily discoverable. It is perfectly indolent in itself, though its weight does sometimes produce some small degree of uneasiness in the back. The great characteristic (as it is called) of this disease, and on which almost all writers have agreed to lay the greatest stress, and to rest their proof of the nature of the disorder, viz. the transparency of the tumour, is the most fallible and uncertain sign belonging to it; it is a circumstance which does not depend upon the quantity, colour, or consistence of the fluid constituting the disease, so much as on the uncertain thickness or thinness of the containing bag, and of the common membrane of the scrotum.

If they are thin, the fluid limpid, and the accumulation made so quick as not to give the tunica vaginalis time to thicken much, the rays of light may sometimes be seen to pass through the tumour; but this is accidental, and by no means to be depended upon. Whoever would be acquainted with this disorder must learn to distinguish it by other, and those more certain, marks, or he will be apt to fall into very disgraceful as well as pernicious blunders. The colour of the fluid is very different and uncertain: sometimes it is of a pale yellow, or straw-colour; sometimes it is inclined to a greenish cast; sometimes it is dark, turbid, and bloody; and sometimes it is perfectly thin and limpid.

⁴⁹⁵ Different methods of cure in the hydrocele. The methods of cure (as they are called) in this species of hydrocele, though various, are reducible to two, viz. the palliative, or that which pretends only to relieve the disease in present, by discharging the fluid; and the radical, or that which aims at a perfect cure without leaving a possibility of relapse. The end of the former is accomplished by merely opening the containing bag in such a manner as to let out the water; that of the latter cannot be obtained unless the cavity of that bag be abolished, and no receptacle for a future accumulation left. One may be practised at all times of the patient's life, and in almost any state of health and habit; the other lies under some restraints and prohibitions, arising from the circumstances of age, constitution, state of the parts, &c.

⁴⁹⁶ Instruments used in the palliative cure. The palliative cure may be accomplished by a very simple operation. The only circumstances requiring our attention in it, are, the instrument wherewith we would perform it; and the place or part of the tumour into which such instrument should be passed. The two instruments in use, are the common bleeding lancet, and the trocar.

The former having the finer point, may possibly pass in rather the easier, (though the difference is hardly perceptible), but is, in our opinion, liable to inconveniences to which the latter is not. The trocar, by means of its canula, secures the exit of the whole

VOL. X.

fluid without a possibility of prevention; the lancet cannot. And therefore it frequently happens, when this instrument is used, either that some of the water is left behind, or that some degree of handling and squeezing is required for its expulsion; or that the introduction of a probe, or a director, or some such instrument, becomes necessary for the same purpose. The former of these may, in some habits, be productive of inflammation: the latter prolongs what would otherwise be a short operation, and multiplies the necessary instruments; which, in every operation in surgery, is wrong. To which it may be added, that if any of the fluid be left in the vaginal coat, or insinuates itself into the cells of the dartos, the patient will have reason to think the operation imperfect, and to fear that he shall not reap even the temporary advantage which he expected. The place where this puncture ought to be made, is a circumstance of much more real consequence; the success of the attempt, the ease, and even sometimes the safety, of the patient, depending upon it.

Whoever conceives, as many have done, and some still do, that the testicle hangs loose in the middle of the water within the vaginal coat, must also suppose that every part of the general tumour is equally fit and proper for this operation. The idea is erroneous, and the experiment may prove highly mischievous. All the anterior and lateral parts of the vaginal coat are loose and detached from the albuginea; in its posterior and superior part these two tunics make one; consequently the testicle is, as it were, affixed to the posterior and superior part of the cavity of the sac of an hydrocele, and consequently the water or fluid can never get quite round it. This being the state of the case, the operation ought always to be performed on that part of the tumour where the two coats are at the greatest distance from each other, and where the fluid must, therefore, be accumulated in the largest quantity; and never on that part of it where the fluid cannot possibly be. The consequence of acting otherwise must not only produce a disappointment by not reaching the said fluid, but may prove, and has proved, highly and even fatally mischievous to the patient.

⁴⁹⁸ It was a custom formerly, after performing this operation, to make use of fomentations and discutient applications, upon a supposition that by such means a return of the disease might be prevented. Among the old writers are to be found the forms of medicines to be applied to the groin and scrotum, to prevent a future descent of the fluid; but anatomy and experience have proved the falsehood of such supposition, and the absurdity of such applications: the present practitioners content themselves with a bit of lint and a plaster; and if the scrotum has been considerably distended, they suspend it in a bag-truss, and give the patient no farther trouble.

In most people the orifice thus made heals in a few hours, (like that made for blood-letting); but in some habits and circumstances, it inflames and festers: this festering is generally superficial only, and is soon quieted by any simple dressing; but it sometimes is so considerable, and extends so deep, as to affect the vaginal coat, and by accident produce a radical cure. It has also been known to prove still more troublesome, and

42 H

and

⁴⁹⁹ This operation fomentations.

⁴⁹⁹ This operation fomentations.

Practice.

Practice.

and even fatal; but then the circumstances both of the patient and of the case have been particular, and such as required attention.

Every other method of treating this kind of hydrocele, except the puncture, was either originally intended to obtain a radical cure, or, having been found to have been often productive of such, has been by different people ranked sometimes among the palliative, sometimes among the radical, means.

500
Of cures
attempted
by means
of ligature,
canula,
tent, &c.

In many of the old writers are found directions for obtaining the cure of this disease by the use of a seton, a canula, a tent, a caustic, a ligature, an injection, or an incision.

Some of these are adopted or preferred by one, and some by another, according to the theory which they have entertained of the disorder, or to the benefits which they have seen to have accidentally arisen from the use of the said means.

To reduce these under some kind of method, (which the manner of their being delivered to us does in general not very easily admit,) we may say, that the seton, the tent, and the canula, were either originally meant to palliate a disease of which the old practitioners had very disagreeable apprehensions, or that they were made use of upon a supposition that the fluid contained in the cyst was in itself noxious; or that the general habit of the patient was relieved, and many other disorders prevented, by the said humour falling or being deposited in that part; or from an opinion that the cure of it ought not by any means to be hastily or rashly attempted: that the caustic, cautery, and ligature, were designed to prevent the supposed descent of the water from the abdomen into the scrotum; and that the injection was calculated for the constriction of a supposed breach in the lymphatic vessels.

501
Reasons
lauded
against
the use of
the cautery.

Some of these (happily for mankind) are now quite laid aside, the reasons for their use being found to be false and groundless; of this kind are the cautery, the ligature, and the injection. The water is now, by every body who has made any inquiry into the matter, known to be formed and collected in the part where it is found; and not to have fallen into it from the belly: and, though an obstruction in the lymphatic vessels of the spermatic cord, may in some degree prevent the regular and due absorption of the fluid from the vaginal tunic, yet no breach or rupture of such vessels can ever produce the disease in question: the extravasation, in such case, must be in another part; and may possibly cause a hydrocele of the cellular kind, in the common membrane of the spermatic vessels, but which can never be found within the tunica vaginalis.

502
Of the tent
and canula.

The reasons originally given for the use of the tent and the canula, viz. the noxious quality of the fluid, and the necessity of a gradual cure, are now also known and acknowledged to be without foundation; and therefore, though these methods, or methods like these, do still continue to be used, yet it is with another view, and upon other principles: not with intention to lengthen the time of a cure, by making a gradual drain for the prevention of other disorders; but merely to abolish the cavity of the tunica vaginalis, by having excited and maintained such a degree of inflammation and suppuration as shall produce an union between that coat and the albuginea testis.

This is indeed the only rational end which can by any of these means be pursued; for the disorder being absolutely local, and the tunica vaginalis (the seat of it) most commonly somewhat altered from its natural state, by having been distended; unless the absorbent vessels can again be restored to a capacity of doing their duty, (a circumstance which does not very often happen), the arteries will continue to exhale new serum into the cavity, and the hydrocele will still remain, or be renewed in a short time after each discharge.

To obtain this end, two kinds of means are proposed. In the use of one, it is intended, by means of a small wound, to excite such a degree of inflammation, as shall occasion or be followed by a total and absolute cohesion of the tunica vaginalis with the tunica albuginea: in the other, a larger and more free incision is made, whereby the cavity of the former of these coats is converted into a hollow or open sore or ulcer, to be filled up by a new incarnation; or else a part of the said tunic being cut away, its power of again holding the extravasated fluid is equally prevented.

The first, or union of the two coats in consequence of inflammation, has sometimes been found to follow the use of such means as were intended to procure only a temporary relief: it sometimes follows the simple puncture with the trocar or lancet; the ancient method of letting out the water by a small incision frequently produced it; and the seton, the tent, and the canula, though used for another purpose, or at least for other reasons, were found to be followed by it so often, that they soon were ranked among the means for obtaining a radical cure.

They were indeed originally designed to discharge the water gradually; and to continue such a drain from the parts where it had been collected, as might prevent any of the ill consequences apprehended from the removal of the local disorder: but the inflammation which supervened sometimes producing a cohesion of the sacculus to the surface of the testicle, what was originally calculated for a palliative remedy only, was by many adopted for a radical one.

If the event and consequence flowing from these means were as much in our power as they have been said to be, that is, if we could with any tolerable precision or certainty determine the degree of inflammation to be excited, and the effect of such inflammation on the vaginal coat, there would be no doubt of the utility of them; but this is far from being the case: for although it sometimes is sufficient for the purpose wished for, and rises no higher than just to a degree equal to that purpose, yet it also frequently happens, that either such degree and extent of it is not excited, or it rises much higher and proves much more painful and fatiguing than was promised or intended; or, after a great deal of pain and confinement, a partial cohesion only has been the consequence, and the disease has still remained, notwithstanding all the patient's and our trouble. Sometimes the pain, inflammation, and symptomatic fever, are but little; but, on the other hand, they are all three sometimes so great as to become alarming, at least to a patient who has been taught to expect a cure upon much more easy terms. The whole scrotum sometimes becomes excessively inflamed, and, after a good deal of pain and trouble, large

503

use of these
methods.

Practice.

Practice.

large sloughs are produced, and the process becomes as irksome as any of those whose event (with regard to a cure) is much more certain.

If the inflammation be but slight, the pain and tumefaction moderate, the symptomatic fever light, the suppuration small, and an universal cohesion of the two membranes is produced, the event is very fortunate, and a very troublesome complaint is thereby got rid of upon very easy terms. If either the inflammation be confined to the dartos, where it sometimes produces several superficial abscesses (of no consequence toward the cure of the disease), or if it has been so partial as only to have occasioned the cohesion between the tunics of small compass, the cavity will not by this means be abolished, nor any thing like a radical cure be obtained; consequently the patient will have undergone all the fatigue, confinement, or pain (be it more or less) for nothing: but if the inflammation rises high, if the scrotum swells considerably, and large deep sloughs are formed (as sometimes happens), the symptoms and the hazard are then fully equal to what attend those more certain methods. Which of the three will be the event, no man can say. Under the same external appearances, different people are more or less liable to inflammation and fever: the confinement of matter, in consequence of too small an opening, will in some habits make strange havoc in a very short time; and if a large opening and a plentiful suppuration must at last be submitted to, the method by a large incision at first is preferable, as the cure is more certain, and the loss of time less. Different circumstances in the patient will render one method preferable to and more likely to succeed than another; but whenever a cure is attempted by any of the before-mentioned means, the uncertainty of the event should be made known, and the patient be apprised of what may happen either with regard to trouble or disappointment.

504
Of the radical cure.

All the methods hitherto taken notice of are calculated to produce a perfect or radical cure, without making a large wound, or bearing the appearance of a surgical operation: those of which we are now to speak, are intended for the same purpose; but by making a large and free opening into the bag containing the fluid, to render the accomplishment of such purpose more certain.

505
Method of curing by caustic.

These are called the cure by *caustic* and the cure by *incision*. The cure by caustic is calculated to spare the terror which a cutting instrument always conveys, and (as the patrons of it say) to avoid the painful symptoms and hazard which frequently attend a large incision in these parts. The method is this: A piece of the common paste caustic, rather less than a finger's breadth, properly secured by plaster, is applied the whole length of the anterior part of the tumour, which will necessarily make an eschar of proportional size. When this eschar either casts off or is divided, an opening of nearly the same length and breadth is thereby intended to be made into the cavity of the tunica vaginalis testis; by which means an opportunity is given to the surgeon to apply such dressings to the inside of the said tunic as shall, by the generation of new flesh, fill up and abolish its cavity. The preference which some practitioners have given to this method before that by incision, has been upon a suppo-

sition, that a circumstance, which very seldom happens will most frequently occur; we mean the penetration of the caustic through the vaginal tunic containing the fluid.

By this they hope to avoid the symptoms which are supposed to be generally excited by the division of the said bag by a cutting instrument; but this the caustic very seldom does. If the tumour be very large and full, the containing parts be very much on the stretch, and the skin and dartos very thin, the caustic may now and then penetrate through to the vaginal coat: but this, whatever may be thought or pretended, very seldom happens; and when it does not, the tunica vaginalis must be divided in the same state and manner as if no caustic had been applied. All the difference between the two methods (caustic and incision) will then amount to this: That in the former, the skin being mortified, the patient is freed from a part of his apprehension at its being cut; and the surgeon, fancying that his escharotic has gone through the vaginal coat, will divide it as a part of the eschar: but a more careful examination of what he is about at the time of such operation, would generally convince him that he divides the bag unaltered by the caustic; and the symptoms which often attend this process confirm it. It has indeed been proposed to divide the eschar made in the skin down to the surface of the tunica vaginalis, and then by the application of a fresh caustic to make an eschar in that coat also. But whoever makes or submits to this experiment, will find, that of two evils he chooses the greater; and, to avoid the pain of incision, incurs a much greater degree of it by the repetition of the escharotic. The pain attending the first application of the caustic is indeed to some persons but little; but in many it is fully equal to that of the knife, and must always be of much longer duration: if it does not penetrate the tunica vaginalis, that bag must be divided by a cutting instrument, (as we have already said), in the same state as if no caustic had been applied; which incision is and must be accompanied with the same symptoms (in the same person) as in the operation by the knife only. Nor can we at all times confine the caustic, so as that it shall not cause a much larger sore than is intended or can be necessary.

Upon the whole, the cure by caustic, as it spares the terror and apprehension of a bloody operation by the knife, and as it requires no dexterity in the operator, may, on those two accounts, become preferable both to many patients and surgeons: yet whoever promises to perform, or expects to receive, a radical cure by caustic upon much easier terms than by incision, will most frequently be disappointed; that is, they will frequently find the fever and inflammatory symptoms full as high, and the sore full as painful, in the one as in the other, and consequently all their care and attention to obviate mischief full as necessary. Neither is the necessary confinement, in general, at all less in the one than in the other.

The method of performing the operation by the knife is as follows: Having appointed an assistant to grasp the upper-part of the tumour, in order to restrain it tense below, a puncture should be made in the lower and anterior part through the skin and vaginal coat. If the operator intends to finish the incision

509
Of performing the operation by the knife.

with a knife, he should make this puncture large enough to admit the end of his fore-finger; which he should introduce immediately before the water is all discharged and the vaginal coat collapsed; and upon that finger so introduced, he should continue his division of the whole length of the bag and of the scrotum which covers it. If he intends to use the probe-scissors (a more tedious and a more painful method), he may make his first puncture with a lancet, and then introduce his scissors. Upon the first division, the water rushes out, and the tumour subsides. If the puncture be made small, a part of the fluid will insinuate itself into the cells of the dartos; and by the immediate collapse of the vaginal coat, the operator will find some difficulty in introducing either his finger or his instrument into the orifice made in it. If he does not do this, he will divide only the skin and dartos, and the patient must undergo a second incision for the division of the cyst: all which inconvenience may be avoided, by making the first opening large enough for the introduction of the finger; and when that is in, all the rest is upon that very easily executed.

308
Treatment
of the testicle
and
wound after the operation.

When the vaginal tunic is divided, and the fluid thereby discharged, the testicle, covered only by its tunica albuginea, comes into view; and, if the incision was either begun or continued very low, it generally thrusts itself out from the wound. This should be gently replaced; and if the vaginal coat is not much thickened by having been long distended, nothing more need be done than to lay a small quantity of fine lint into its cavity, and then, covering the wound with a large pledget and a soft bolster, tie the scrotum up in a suspensory bag. This operation, if properly performed, may be executed in a very few seconds: it requires no other violence than the mere division of the parts; and if this division be made with a knife rather than scissors, it will require much less time, and cause much less pain.

The membranous structure of the parts on which this wound is inflicted, their continuation from the peritonæum, and the great irritability of some of those which are necessarily laid bare, and put under a necessity of receiving dressings, must occasion pain and symptomatic fever: this it is the business of art to moderate and relieve; phlebotomy, lenient aperitives, febrifuges, and opiates, will therefore become necessary. But in this case, as in many others, it will generally be found much more easy to prevent bad symptoms, than to remove them when they have been permitted to attain a considerable height. The operation is, or ought to be, confined to the young and the healthy, in whom inflammatory symptoms are most likely to occur; but (we may venture to say) to whom we have more efficacious remedies to apply in such disorders, than can be used to people of a different habit and in different circumstances.

The general induration of all the parts about, the thick tumid lips of the incision, and the general inflammatory enlargement of the scrotum, have, for the first four or five days, a disagreeable appearance; and may, if neglected or wrong treated, prove very troublesome or even hazardous; and the kind of discharge which during that time is made (a thin discoloured gleet), seems very unequal to the reduction of so much tumefaction: but when the febrile symptoms

are appeased, and a kindly suppuration is begun, let the surgeon have patience, and not by an over-officiousness, or by improper dressings, interrupt nature in what she is about: let him, by warm fomentations, keep the parts clean and perspirable; let him dress the wound with a small quantity of soft easy digestive applications, and, covering the whole scrotum with a soft warm poultice, suspend it in a proper bag, and he will in general soon see a favourable change in all the appearances; he will see the inflammation disappear, the tumour resolve, and all the tumefaction in due time subside. But if he neglects these general cautions, and, under a notion of assisting digestion, goes to work with precipitate and other irritating dressings, the face of things will not be so agreeable: the tumour will not subside; and he will continue, or rather create, a painful undigested sore, with all its consequences; but for which he only is accountable.

In about six weeks the scrotum is generally reduced to nearly its natural size; and when the wound is quite healed, the cicatrix is a mere line, correspondent to the original incision; which is a circumstance of more consequence to the patient than is imagined, especially if he be obliged to get his bread by labour.

If the tunica vaginalis containing the water, by long or frequent distention or from any other cause is become thick and hard, and cannot therefore contract itself or be contracted upon the evacuation of the fluid, it will contribute considerably to the thickness of the lips of the wound, as well as to their hardness, pain, and difficulty of digestion. In this case, the best way is to remove a part of it on each side at the time of the operation. The cellular structure of the dartos easily admits this to be done; and when these sides are thus taken away, the lips of the wound consist only of the common integuments. A knife will do this with much more ease and expedition than any other instrument whatever. The method proposed by the late Mr Douglas, of doing it by repeated snips of the probe-scissors, is operose, unhandy, and unnecessarily painful and tedious; nor is the cutting away an oval piece of the scrotum, as advised by that gentleman and some others, at all necessary: on the contrary, the more loose that part of the scrotum is which is to cover the testicle (now deprived of its vaginal coat) the better, as it will be more capable of corrugation.

With these cautions, and under the proper restrictions already mentioned, this method of obtaining a radical cure is very practicable. That it is sometimes accompanied by troublesome symptoms, is beyond all doubt; and so is the method by caustic. We cannot say that we have never seen it prove fatal; nor can that be said of any operation of consequence: much depends on the choice of a proper subject, and the observance of the necessary means and cautions; without which, both this and the use of the caustic will always be troublesome, and sometimes hazardous.

When the quantity of fluid is large, and the scro-⁵⁰⁹ticum and tunic much on the stretch, Mr Pott thinks the water by mere puncture, ^{ter by} ^{puncture is} ^{sometimes} it is better to discharge the water by mere puncture, and not to perform the operation for the radical cure until a fresh accumulation has again moderately distended it. The inflammation necessarily consequent ^{upon}

Practice.

Practice.

upon the division of these parts; just after they have been so much on the stretch, and so suddenly let loose, may be productive of worse symptoms, and a higher degree of fever and tumefaction, than usually occurs when the same parts are divided in a less distended state.

In this operation, the point to be aimed at, as Mr Pott observes, is to excite such a degree of inflammation, both in the tunica vaginalis and tunica albuginea, as shall occasion a general and perfect cohesion between them: and this, if possible, without the production of slough or abscess, without the hazard of gangrene, and without that degree of symptomatic fever which now and then attends both the caustic and the incision; and which, when it does happen, is so alarming both to patient and surgeon.

510
Of the use
of a seton.

These ends he has frequently obtained by the use of a seton. It is a method of cure mentioned by Aquependens, as used by Guido and others before him, (though their process was somewhat different from his.) He has several times tried it on subjects of very different ages, some of them more than 50 years old. It requires confinement to bed only for a few days; after which the patient may lie on a couch to the end of the attendance, which is generally finished in about three weeks or a month at the farthest; and during all that time no other process or regimen is necessary, than what an inflammation of the same part from any other cause would require.

SECT. XV. Of Trepanning.

THERE appears scarce any part of the cranium, from the frontal sinuses to the insertions of the muscles into the occipital bone, that may not be perforated with safety. There are some late instances in this kingdom, where the trepan has been successfully applied to the frontal sinuses. How far it might be practicable to separate the muscles from and apply the trepan to the inferior part of the occipital bone, almost to the foramen magnum, may be worth future consideration; as^s it is no unreasonable supposition, that a case may happen to be so circumstanced as to admit of no other remedy; and, according to Celsus, a doubtful one is better than none (a).

The parts of the skull not eligible for the application of the trepan are, 1. The frontal sinuses. 2. The futures, in young subjects; for in old ones the adhesion of the dura mater to them is but little more than to other parts of the cranium. 3. The middle of the os frontis, towards the nose, where the spinal process of that bone projects considerably. 4. The anterior and inferior angles of the parietal bones, on the internal parts of which run the arteries of the dura mater. 5. The sagittal future, on account of the longitudinal sinus running immediately under it. 6. The lambdoidal future, under which lies the course of the lateral sinuses. 7. The occipital bone, on account of its great inequality of thickness, and irregularity of its internal surface. 8. The os temporale, as the temporal muscle must unavoidably be wounded in making room for the trepan: and lastly, we must be careful, not to apply it to a yielding fractured part of the bone, that

511
Parts of the
skull not
eligible for
trepanning.

will not resist the necessary force in making the perforation.

There are, however, instances from the best authorities, of the successful application of the trepan to all these exceptionable parts, sufficient to encourage a cautious and judicious practitioner upon emergencies; to which, says Mr Gooch, I will venture to join my own experience, hoping it may have some weight in determining a matter of so much importance to surgery. The frontal sinuses have been trepanned with success in London and Paris. Perforations may be made lower down the os frontis in children than in adults, without running the hazard of falling upon the sinuses; for they gradually enlarge, extending higher up as they arrive at puberty. Mr Gooch has applied the trepan near the middle of the os frontis, without meeting with any obstacle from the spinal process: and at the anterior and inferior angles of the parietal bones, without opening the *art. dura matris*. The operation has been performed by Mr Warner upon the sagittal future, when bits of bone stuck in the longitudinal sinus, which he easily extracted after enlarging the wound with his lancet, stopping the hæmorrhagy with dry lint without any difficulty.

After having deliberately considered every circumstance, and resolved upon the operation, the instruments, sponges, dressings, compresses, bandage, and every necessary thing, are to be disposed in perfect good order, that the operator may have nothing to seek when he wants it. The head is to be shaved, if it has not been already, as indeed it should all over immediately after any of the preceding accidents: it is then to be rested and firmly held upon a person's knees; and, with the knife appropriated to this use and the scalpum, a piece of the scalp is to be removed, of a circular, elliptical, or other figure, as the circumstances of the case require. The scalping should be of such extent, as may give a fair opportunity of making as many perforations as shall be found necessary, as far as the surgeon's judgment and observation can direct him. He ought not to be sparing in this respect, lest he should be under the disagreeable necessity of extending the incision farther. The manner of cutting, is to apply force enough to the knife, to carry it quite through to the bone at once, not bearing too much upon the point, especially if we cut over loose fragments, which we should endeavour to avoid; the edge of the knife should be so inclined, as to cut rather more of the pericranium than the skin. When we have proceeded thus far, the pericranium is to be raised a little, with the point of the knife, quite round the incision; and then the scalpum used, which will be found the best instrument to clear the bone of that membrane, as has been found by frequent experience. Should it be thought proper to proceed immediately to trepanning, if any considerable vessels have been divided in scalping, they must be secured by needle and ligature; but when we do not intend performing the operation directly, dry lint with compress and bandage is generally sufficient to restrain the hæmorrhagy; but sometimes the pressure of an assistant's fingers upon it will serve that purpose without a ligature.

(A) Bontius, a writer of the best credit, relates a singular case of a sailor, whose head was crushed between the ship and a boat; in consequence of which dreadful accident, the greater part of the occipital bone was taken away in fragments, almost as far as the foramen magnum, and the patient perfectly cured by him and another surgeon.

Practice.

ture, when we determine to proceed to the operation directly.

514
The trephine the most eligible instrument.

That kind of trepan called the *trephine*, is now in general use in all places: it is more commodious than the other, and can be better managed and regulated in the operation, as the different bearings may require; and it will cut full as fast, being worked both backwards and forwards. Before the operation is begun, the patient's head must be fixed so that the light may fall properly upon it, and in such a convenient position, that the instrument may be placed perpendicularly upon the part; and of such a height and manner, that the attitude may be easy during the operation, which often proves tedious, requiring many perforations (s).

515
Of the posture of the patient's head, working of the saw, &c.

Whether the patient has the operation performed in bed or seated in a chair, it is always found that resting his head on a pillow, with a board underneath it, upon the knees of an assistant, is preferable to any other manner; for being thus placed, the assistant will have more power to keep it steady, to resist the motion of the instrument. When the head is well adjusted, the next step is to make a hole with the perforator, deep enough to fix the central pin of the trephine, in order to prevent the saw from slipping out of its circular course, till it has formed a sulcus sufficiently deep to be wrought steadily in; and then the pin is to be taken out. If the skull is thick, the teeth of the saw must be brushed clean now and then during the trephination; and dipping it into oil as often, will greatly facilitate the motion, and expedite the operation, making it less disagreeable to the patient if he has his senses; and, in order to lose no time, it would not be amiss to be provided with two instruments of the same size.—We must remember, after having made some considerable progress in the operation, to examine the sulcus often with a picktooth, or some other proper instrument, in order to discover where the bearings are necessary to be made.—These precautions are of more consequence when we are employed in perforating a part of the skull that we know has an unequal thickness, especially after having passed the diopée. And though we are told by writers in general, that we may saw boldly till we come at the diopée, generally to be known by an appearance of blood, yet we should be upon our guard in this point; examining if the piece be loose, when we have sawn some way into the bone, lest we should happen through inadvertence to wound the subjacent membrane; for in some parts of the skull there is naturally very little diopée, and in old subjects scarce any remains to afford direction to our judgment by the bloody appearance. And for the same reason, it is also to be remembered, that childrens skulls are very thin.—When the piece is quite loose, it is to be taken out with the forceps contrived for this purpose; and if the lower edge of the perforation is left jagged, it is to be smoothed with the lenticular, that it may not irritate the dura mater. The next step is to raise the depressed piece or pieces of the cranium with the

elevator; or to extract the fragments of the bone, grumous blood, or any extraneous body, with proper instruments. After this, if there appears good reason to apprehend that blood, lymph, or matter, is contained under the dura mater, we should open it directly with a lancet very cautiously; endeavouring to avoid the blood-vessels ramified upon it, and those which lie immediately under it: and, on this occasion, it will be prudential to conceal the instrument as much as we can, by wrapping it all round with tow almost to the point, in order to prevent impressions being made upon the spectators to our prejudice.

When we have recourse to the trepan, on account of a fissure in which the bone will not yield, we should apply the instrument so as to include part of it, if not directly over it, as it is most likely the extravasated blood or lymph should be found directly underneath it: and when the fissure is of great extent, it may be proper to make a perforation at each end, if the whole can be conveniently brought in view; and, in some cases, more perforations may be requisite, according to the course of it, even to its full extent.

When we propose to make several perforations, in order to remove depressed fragments of the bone that are firmly fixed, and having the internal surface larger than the external, or to raise them sufficiently, it is necessary to apply the trepan as near the fractured parts as they will admit of; making the perforations adjoining, to save the trouble of cutting the intermediate spaces with the head-saw: and, as before hinted, we should invariably observe to make the perforations in the most depending parts we can, for the same reason as we endeavour to obtain depending openings in the fleshy parts. And in perforating the skull, where there is great inequality of its thickness, it appears more advisable to raise the piece before it is cut quite through in every part of it, to obviate injuring the subjacent membrane with the saw.

When the skull has suffered an injury upon a future, and it is not thought advisable to use the trepan there, especially in young subjects, in whom the dura mater adheres more strongly than in adults, as has been remarked, we should always remember to make a perforation on each side of the future; for this obvious reason, because there cannot be a free communication between the one side and the other, on account of the attachment of that membrane to the future.

After the elevation of the fragments of the bone, or the removal of them, the extraction of extraneous bodies, and the evacuation of extravasated blood, lymph, or sanies, &c. the membranes may be dressed with *unguent. à gum. elemi*, extolled by Franciscus Arceus, the inventor of it, made of a softer consistence with *half. à copaib.* or some other natural balsam; applying it just warm with a feather, and soft lint lightly over it, dressing the other parts as we have already directed in wounds of the head: after which, it may be proper to embrocate the whole head with *ol. et acct. adding a little spirit. lavend.* and to apply

(n) Scultetus says, he was obliged to make 7 perforations in a fracture with great depression. Glandorp says, his master Spiegelius made the same number upon the like occasion. Bionia made 12. Hilpount of Nassau had 27 made in different parts of his head by Henry Chadborn, a very eminent surgeon; and that nobleman has attested the cure under his own hand. Mr Gooch made 13 in the case of an old man, with success, as related in his Cases and Remarks on Surgery.

Practice. ply a plaster of *cerat. alb.* or some such easy application, with gentle compresses and bandage. The proper bandages upon this occasion are what the French call the *grand couvre-chef*, and the *capeline* or *reflex bandage*, which require great care and exactness in their application, for the patient's ease. A bandage with six tails, or a kind of coif with lappets affixed to it, may be found very applicable in some cases; but to serve this purpose, the surgeon must occasionally exercise his invention.

After the dressing, the patient is to be placed in as easy a position in his bed as possible, with his head and shoulders elevated a little more than ordinary; and the rules we have laid down in the cure of wounds are to be duly observed. Warmer applications and bandages are required in winter than in summer. The degree of heat in the room must be regulated according to the temperature of the season; and it is necessary to exclude the light. In injuries of the head, bad symptoms are apt to come on sooner in warm, moist, sultry weather, than in a cold season, when it may be very beneficial to make the circumambient air warm, and dress the wound as expeditiously as possible, defending it from the attack of the cold air. A strict regimen and observance of the non-naturals are now of the greatest importance to be attended to; for a slight transgression therein may prove of fatal consequence, as we have amply evinced.

When the digestion of the wound proves kind, we shall soon observe granulations of flesh, of a good complexion, shooting from the extremities of the vessels, and throwing off the parts of the dura mater that may have suffered; which, by extending themselves and twisting one with another, form in the aperture a substance having the appearance of flesh. The same operation of nature, in a longer time, throws off exfoliations from the circumference of the perforation and other parts of the denudated skull, thicker or thinner, sooner or later, according to the age and constitution of the patient, the degree of injury the substance of the bone has sustained, the season of the year, &c. The granulations which arise from the different parts, uniting together, constitute the organized or vascular carnosous substance, which is called the *incarnation* of the wound: and this regenerated substance, in young subjects, generally acquires a perfect bony hardness in the perforation, but seldom in old persons.

In order to remove the fungi mentioned, n° 132. ligature, excision, and escharotics, have been recommended; and sometimes practised with fatal effects, throwing the nervous system into great disorder. And as there is so much to be apprehended from these methods, we should by all means take early care to prevent the growth of such excrescences; which, if neglected, may increase to a great size in a short time.

The best method of doing this is, first to apply to the dura mater a sindon, spread with the balsam recommended, or dipped into it, moderately warm, according to the state the membrane appears in: then a plate of lead is to be exactly adjusted in the perforation upon the sindon, having the ears of it turned back upon the skull; over which a compress, consisting of a few doubles of common plaster, with a

piece of very thin sheet-lead or card interposed, is to be laid; filling the wound up with even lint, rather above the level of the scalp; then a small easy compress of cloth, faced with *cerat. alb.* is to be applied, with a piece of card or thin stiff paper on the outside of it; over which, strips of common plaster about an inch broad are to be laid crucially, extending two or three inches beyond the compress. By this means the plate will be properly confined, and the degree of pressure may be easily regulated, without inconvenience to the patient, or interrupting the discharge at the wound; and should a greater degree of pressure be required, it may be obtained by thickening the compress, and making one of the strips of plaster pass through a slit in the other, as in the uniting bandage. After proceeding thus far, the head is to be embrocated, and a large thin compress spread with *cerat.* applied over the crucial plasters, with easy bandage, as before directed. When the dura mater is granulated with flesh, the sindon or lint, moistened with a mixture of *tinct. myrrhæ* and *aq. calcis*, is a good application; and the other parts of the wound are also to be attended to, according to the rules of surgery which we have before laid down, in order to prevent the luxuriance of flesh, till the exfoliations are completed; for should this point be neglected, and loose flesh suffered to creep upon the bone from the circumference of the wound, much inconvenience and trouble, besides pain to the patient, might proceed from such inattention.

An abatement of the symptoms after the operation, with a good aspect of the wound in a healthy subject, give us reason to hope for success; but if the symptoms continue threatening, with a diness, glassy appearance, or livid colour of the wound, or a discharge of a feid gleet from the membranes or brain, they are to be looked upon as very bad omens: however, we are to omit the use of no rational means, having instances upon record of the happy event of the most alarming cases to encourage our perseverance. The symptoms after the operation may require frequent bleeding, as well as strict regimen.

Should the patient, at any time after the cure, complain of pain or disorder in his head, with symptoms of plenitude, recourse ought to be had immediately to bleeding and gentle purging, with the observance of a spare diet; and for some time after his cure, he should also be very exact in his regimen and government of himself, both as to body and mind. It will be likewise very prudent to wear for a considerable time a thin brass, steel, or tin plate, to defend the part against external injuries, especially if there has been any great loss of the bone; under which circumstance, in old persons, such a defence may be found necessary for life.

SECT. XVI. Of Tumours on the Heads of new-born Children.

THIS kind of tumour proceeds from an extravasation of blood; probably in consequence of some injury in a laborious, hasty, or injudicious delivery; as the heads of children are so tender, and the vessels so delicate, that time should always be allowed for a gradual dilatation of the parts, to admit of the exclusion of the fetus with safety. It is seldom observed on any other parts

518
Of the method of preventing fungi.

519
Causes of tumours on the heads of children.

of the head than the parietal bones; and the extravasated blood is most frequently lodged between the pericranium and the cranium.

§20
Description of the tumours.

This tumour is generally circumscribed by a ridge, when the extravasated fluid is contained between the cranium and the pericranium, and feels as if there was a depression or deficiency of the bone; but the deception is owing to the fluid in the distended pericranium yielding to the fingers, and to the ridge circumscribing the tumour, which, without very accurate examination, may be taken for the edge of the bone.

Some surgeons have looked upon this sort of tumour as an aneurism proceeding from the inside of the skull, others as a hernia of the brain. But was either of these the case in question, it must appear between, and not upon, the bones it does; and a pulsation would be observed in it.

§21
Method of cure in the foundling-hospital.

The surgeons of the foundling-hospital, who have had the greatest opportunities of discovering the nature of these tumours, and the best method of cure, from their large experience, say, they generally succeed by opening them, in case the children were otherwise healthy; and that they prefer this method, rather than waiting in expectation of absorption by any other, apprehending that the bad consequences they have seen may proceed from the putrid quality of the fluid contracted by its stagnation. They make an incision the whole length of the tumour; lay soft dry lint under the edges of the wound, to favour the discharge of the extravasated blood, after pressing out as much as they can without bruising the tender parts; and then apply a pledget of common digestive over the lint, with easy compresses and bandage.

§22
Another method.

Some other practitioners, of experience too, are against opening these tumours; advising the application of compresses, moistened in warm austere red wine, or red wine and vinegar, to be renewed as often as they grow dry; and say they have generally observed absorption of the fluid to be the effect of this method without bad consequences. However, should there appear no diminution of the tumour by regularly pursuing this method a reasonable time, it will then certainly be advisable to open it, lest the fluid should be absorbed in a putrid state, or the bone injured by it, whence bad consequences might ensue: and if the bone received an injury originally, the necessity of opening is indisputable.

SECT. XVII. Of the Cataract, cutting the Iris, and Operation for the Fistula Lacrymalis.

§ 1. Of the Cataract.

The cataract, called by the Latins *suffusio*, is a disease of the crystalline humour, rendering the whole body of it opaque; so that the rays of light which, in the natural state of its transparency, were transmitted to the tunica retina, become now totally intercepted, and produce no effect. This is pretty nearly the account delivered down to us by Hippocrates and the ancient Greeks, who likewise knew it by the name of *glaucoma*.

§23
The cataract a disease of the crystalline humour.

Anatomists have frequently dissected the eyes of persons under this disorder after their death; and have found it to be always an opacity of the crystalline humour, agreeably to the definition of a glaucoma: so

that by consequence we must understand the words *cataract* and *glaucoma* as synonymous terms.

§24
Different colour of cataracts.

The general criterion of the fitness of cataracts for the operation is taken from their colour: the pearl-coloured, and those of the colour of burnished iron, are esteemed proper to endure the needle; the white are supposed milky, the green and yellow horny, and incurable.

The depression of a cataract of any colour would be the cure, if that alone was the dis temper of the eye; but it generally happens, that the yellow cataracts adhere to the iris so firmly as to become immovable; besides, when they follow in consequence of a blow, which is often the case, either the cells of the vitreous humour are so much disturbed and broken, or the retina affected, that a degree of blindness will remain, though the cataract be depressed.

To judge whether the cataract adheres to the iris, if you cannot at once distinguish it by your sight, shut the patient's eye, and rub the lids a little; then suddenly opening it, you will perceive the pupil contract, if the crystalline humour does not prevent the action by its adhesion: and when this is the case in any kind of cataract, the operation can hardly be advised.

Another consideration of the greatest moment, before undertaking the cure, is to be assured of the right state of the tunica retina; which is very readily learnt, where there is no adhesion of the cataract, from the light falling between the iris and crystalline humour, which if the eye is not sensible of, it is a certain indication of another malady, and absolutely forbids the operation. Generally this cataract takes its rise from headaches, convulsions, and nervous disorders.

§25
Method of performing the operation.

When none of these objections forbid the operation, it may be thus done. Having placed your patient in a convenient light, and in a chair suitable to the height of that you yourself sit in, let a pillow or two be placed behind his back, in such a manner, that the body bending forward, the head may approach near to you; then inclining the head a little backward upon the breast of your assistant, and covering the other eye so as to prevent its rolling, let the assistant lift up the superior eye-lid, and yourself depress a little the inferior one: this done, strike the needle through the tunica conjunctiva, something less than one tenth of an inch from the cornea, even with the middle of the pupil, into the posterior chamber, and gently endeavour to depress the cataract with the flat surface of it. If, after it is dislodged, it rises again, though not with much elasticity, it must again and again be pushed down. If it is membranous, after the discharge of the fluid, the pellicle must be more broke and depressed; if it is uniformly fluid, or exceedingly elastic, we must not continue to endanger a terrible inflammation by a vain attempt to succeed. If a cataract of the right eye is to be couched, and the surgeon cannot use his left-hand so dexterously as his right, he may place himself behind the patient, and use his right-hand.

We have not recommended the speculum oculi, because, upon the discharge of the aqueous humour through the puncture, the eye, being somewhat emptied, more readily admits of the depression of the crystalline humour than when pressed upon by the instrument.

§26
Why there is no occasion for using the speculum oculi.

As to the method of testing the succeeding inflammation,

mation, bleeding and other gentle evacuations are found absolutely necessary.

§ 2. Of cutting the Iris.

THERE are two cases where this operation may be of some service; one when the cataract is from its adhesion immovable; and the other when the pupil of the eye is totally closed up by a disorder of the muscular fibres of the iris, which gradually contracting the orifice, at last leaves the membrane quite impermeable. This last distemper has hitherto been deemed incurable. The adhesion of the cataract has also been considered as a species of blindness not to be relieved. But Mr Cheselden has invented a method of making an artificial pupil, by slitting the iris, which may relieve in both the instances here stated.

In doing this operation, the patient must be placed as for couching, and the eye kept open and fixed by the speculum oculi, which is absolutely necessary here; then introducing the knife in the same part of the conjunctiva you wound in couching, insinuate it with its blade held horizontally, and the back of it towards you, between the ligamentum ciliare and circumference of the iris, into the anterior chamber of the eye; and after it is advanced to the farther side of it, make your incision quite through the membrane; and if the operation succeeds, it will upon wounding fly open, and appear a large orifice, though not so wide as it becomes afterwards.

The place to be opened in the iris will be according to the nature of the disease: if the membrane itself be only affected with a contraction, the middle part of it, which is the natural situation of the pupil, must be cut; but if there be a cataract, the incision must be made above or below the cataract, though it is more eligible to do it above.

The contracted iris from a paralytic disorder, is so often complicated with an affection of the retina, that the success is very precarious in this case. This operation has answered best in adhesions of the crystalline humour, though but very seldom even there.

§ 3. Fistula Lachrymalis.

The fistula lachrymalis is generally understood to be such a disorder of the canals leading from the eye to the nose, as obstructs the natural progress of the tears, and makes them trickle down the cheek. Although the seat of this disease is the same in almost every subject, yet its appearance is very different in different persons, and under different circumstances. These variations depend principally on, 1. The degree of obstruction in the nasal duct; 2. The state of the cellular membrane covering the sac; 3. The state of the sacculus itself; 4. That of the bone underneath; 5. The general state and habit of the patient.

Sometimes a serous kind of defluxion, by which the lining of the sac and duct are so thickened as to obstruct or prevent the passage of the fluid through them into the nose, makes the whole complaint; and the cellular membrane on the outside not being diseased, there is no appearance of inflammation. In this case the duct is stopped, and the sacculus dilated, but without any alteration in the colour of the skin; a fungus appears in the corner of the eye next to the

nose; and upon the application of a finger to this tumour, a clear viscid mucus is discharged through the puncta lachrymalia: the patient feels no pain, nor finds any inconvenience, except what is produced by the discharge of this mucus, and by the trickling of the lymph down the cheek.

In some cases the mucus is not perfectly and always clear, but is sometimes cloudy, and looks as if it had a mixture of milk or cream in it: at first waking some of it is generally found in the corner of the eye; and the eye-lashes being smeared over with it during sleep, most commonly adhere together in the morning.

This is the most simple state of the disease, what the French have called the *hernia*, or *hydrops sacculi lachrymalis*. It is frequently met with in children who have been rickety, or are subject to glandular obstructions: and in this state it sometimes remains for some years, subject to little alterations, as the health or habit shall happen to vary, the sacculus being sometimes more sometimes less full and troublesome; the mucus which is pressed out is sometimes more sometimes less cloudy, and now and then it is attended with a slight ophthalmia, or an inflammation of the eye-lids; but which, by common care, is easily removed.

If the sacculus is not much dilated, the discharge small, and produced only by pressure, the chief inconveniences are the weeping eye, and the gumming together of the lids after sleeping: but these, by being attended to, may be kept from being very troublesome; and if the disease makes no further progress, may be so regulated as to render any more painful process totally unnecessary.

If the dilatation is considerable, the swelling is more visible, and the quantity of mucus is larger; it is also in this state more frequently mixt and cloudy, and more troublesome, from the more frequent necessity of emptying the bag; but if the patient be adult, it may, even in this more dilated state of it, be kept from being very inconvenient.

If an inflammation comes on, the tumour is thereby considerably increased, the discharge is larger, as well during sleep as upon pressure; the skin covering it loses its natural whiteness and softness, becomes hard, and acquires an inflamed redness; and with the mucus a mixture of something, which in colour resembles matter, is discharged, especially if the pressure be made with any force or continued for any time. This circumstance, added to the painful sensation and inflamed appearance of the parts, has been productive of a supposition that in this state there is either an ulcer or an abscess within the sacculus or duct. This opinion, though it may possibly sometimes have some foundation in truth, yet is in general entertained much too hastily, and is also the principal source whence most of the mistakes concerning this disease have sprung; but as there is a certain criterion by which we may distinguish between pus and mucus, practitioners cannot now be liable to such errors in this respect as formerly.

The inflammation of the cellular membrane covering the sac is a circumstance which makes a considerable difference both in the appearance of the disease and in its requisite treatment; in some cases it is

confined merely to the surface of the tumour in the corner of the eye; in others it spreads still farther, affecting the eye-lids, cheek, and side of the nose.

When the parts are in this state, the mucus within the bag has generally the appearance of being matter; that is, it wears a deep yellow colour, and is of a more thin consistence: if the puncta lachrymalia are naturally large and open, and the inflammation confined to the surface of the face, its contents will pass off pretty freely, and the skin will remain entire. This is what the ancients called the *simple* or *imperfect*, or *anachylops*.

But when the skin covering the lachrymal bag has been for some time inflamed, or subject to frequently returning inflammations, it most commonly happens that the puncta lachrymalia are affected by it, and the fluid, not having an opportunity of passing off through them, distends the inflamed skin, so that at last it becomes sloughy, and bursts externally. This is that state of the disease which is called perfect *Anachylops* or *Eggleps*: the discharge which used to be made thro' the puncta lachrymalia, while the skin was entire, is now made through the new opening, and, by excoriating the eye-lids and cheek, increases the inflammation, and gives the disease a much more disagreeable appearance. In some, the matter bursts through a small hole; and after it has discharged itself the tumour subsides, the neighbouring parts become cool, and though the skin covering the surface of the sacculus is sloughy and foul, yet there is no reason to believe that the sac itself is much diseased below. In others the breach is large, the skin remains hard and inflamed, and, from the appearance of the fore, there is reason to suppose the whole inside of the bag to be in a diseased state; and in some cases which have been much neglected or irritated by ill treatment, the cavity of the sacculus seems to be filled with a loose ill-conditioned fungus, which gleets largely, and produces inflammation and excoriation of all the parts about.

559
In what
cases a car-
ries of the
bone attends
this disease.

There is also another circumstance which sometimes is found to attend this disorder, viz. a carious state of the bones. This was by our forefathers supposed to be a frequent one, and was the principal reason for their so free use of caustic, cautery, and scalpra, in the treatment of it; but since the disease has been more minutely examined into, this circumstance has been found to be a very rare one. When the fistula lachrymalis is a symptom of the lues venerea, as it sometimes is, the bones are indeed often carious; but then the fistula is not the original complaint, but produced secondarily, and is a consequence of the diseased state of the os ethmoides and ossa spongiosa of the nose, and is not curable by any local means or applications, but depends entirely on the cure of the disease of which it is a symptom.

An abscess after the small-pox, by falling on the lachrymal bag, has made it all slough away, and leave the bones bare; which circumstance also sometimes attends the free use of strong escharotics applied to destroy what is called the *cyst*; but without the accession of some other disorder producing it, or the most absurd method of treating the complaint, a caries of the bones will very seldom be met with. Indeed the combination of other diseases, either of the general habit, or affecting the same or the neighbouring parts, does

often make a very material difference, both in the appearance of the disorder, in the prognostic, and in the proper method of treating it; which therefore should always be inquired into. For instance, the patient is sometimes subject to an habitual ophthalmia or lippitudo, which will add to the deformity, and give a good deal of additional trouble during the cure: an ozena, or some other disease of the membrane and cells of the ethmoid bone, or a polyposus excrescence within the nose, are now and then combined with it. The habit is sometimes, as we have before observed, infected with the lues venerea, of which this disease may be a symptom: stremous glandular obstructions are its too frequent companions; and, what is worst of all, it is sometimes cancerous.

From what has been said, we may divide this disease into four general heads or states, under which all its lesser distinctions may be comprehended. The first consists in a simple dilatation of the sacculus and ob-
struction of the nasal duct, discharging upon pressure a mucus, either quite clear or a little cloudy; the skin covering the bag being entire and perfectly free from inflammation. In the second, the tumour is somewhat larger; the skin which covers it is in an inflamed state, but entire; and the discharge made through the puncta lachrymalia is of a pale yellow or purulent colour. In the third, the skin covering the sacculus is become sloughy, and bursts; by which means the swelling is in some measure lessened: but the mucus, which while the skin was entire used to be pressed out through the puncta lachrymalia, now discharges itself through the new aperture. The ductus ad nares, both in this and the preceding state, are not otherwise diseased than by the thickening of its lining. In the fourth, the passage from the sacculus lachrymalis into the nose is totally obliterated, the inside of the former being either ulcerated or filled up with a fungus, and attended sometimes with a caries of the bone underneath.

The ancients, who supposed this disorder, in its first state, to be an inflammatory effluxion from the brain on the caruncle, tending to suppurate, directed their first attention to prevent such consequence: for which purpose they employed phlebotomy, cathartics, issues, setons, collyria, and refrigerant applications of all sorts; and these not succeeding, they had recourse to such as they thought would hasten the suppuration of the supposed abscess.

By the improper use of medicines of the latter kind, it frequently happened that the skin became inflamed and burst: the discharge which necessarily followed this accident, together with the heated appearance of the parts about, confirmed their opinion of a collection of matter within; and, according to such supposition, they attempted to obtain a cure by dilating the orifice, and endeavouring to make an incanation from the bottom of the hollow. Not being acquainted with the situation or use of the nasal duct, they took no care to free it from the obstruction under which it laboured; but, dressing the fore like a common imposthumation, permitted it either to be filled up with a loose fungus, or to contract itself to a narrow fistulous orifice; which daily discharging a discoloured kind of fluid, and not healing by such means as they made use of, they concluded the bone underneath was
carious.

carious, and made way down to it, either by removing the parts with a cutting instrument, or by destroying them with caustic and cautery, intending to procure an exfoliation, and thereby a firmer basis to heal on.

But since the use of the ductus nasalis has been known, since it has been discovered that an obstruction in this is the primary and principal cause of the disorder, and that what passed for the cavity of an abscess is really the facculus lachrymalis, both the intention of cure, and the means, have been considerably altered.

In the first and most simple state of the disease, viz. that of mere obstruction without inflammation, much pains have been taken to restore the parts to their natural state and use, without making any wound or division at all; the introduction of a probe, the injection of a fluid, and a constant compression made on the outside of the facculus in the corner of the eye, are the principal means by which this has been attempted.

Some few years ago, M. Anel made a probe of so small a size as to be capable of passing from the eyelid into the nose, being introduced at one of the puncta lachrymalia, and passing through the facculus and duct; with which probe he proposed to break thro' any small obstruction which might be found in its passage. He also invented a syringe, whose pipe is small enough to enter one of the puncta, and by that means to furnish an opportunity of injecting a liquor into the facculus and duct; and with these two instruments he pretended to be able to cure the disease whenever it consisted in obstruction merely, and the discharge was not much discoloured. The first of these, viz. the passage of a small probe through the puncta, has a plausible appearance; but will, upon trial, be found very unequal to the task assigned: the very small size of it, its necessary flexibility, and the very little resistance it is capable of making, are manifest deficiencies in the instrument; the quick sensation in the lining of the sac and duct, and its diseased state, are great objections on the side of the parts; supposing it were capable of answering any valuable end, which it most certainly is not.

That the passing a fine probe from one of the puncta lachrymalia into the nose is very practicable, is known from experience; but the pain it gives, and the inflammation it often excites, are much greater than any benefit which does or can arise from it.

It is said, that the principal use of this probe is to clear the little ducts leading from the puncta into the facculus, and the obstruction of those ducts is often mentioned as a part of this disease. Hence one would be led to suppose that it was a circumstance which frequently occurred; whereas it is seldom, if ever, met with. Nor, even if it did happen, could it ever produce the disease in question; the principal characteristic of which is a discharge into the inner corner of the eye upon pressure made in the angle. This discharge is made from the facculus through the puncta, and proves that the latter are open. The passing a probe, therefore, through these, seems to be perfectly unnecessary, since a stoppage of them would never give rise to that disease, which consists in an obstruction to the passage of any thing from the sac into the nose, and not from the eye into the sac.

The syringe, if used judiciously while the disease is

recent, the sac very little dilated, and the mucus perfectly clear, will sometimes be found serviceable; it gives no pain; and a few trials render the use of it very little troublesome.

Fabricius ab Aquapendente invented an instrument, which was so contrived, as by means of a screw to make a pressure externally on the lachrymal bag; from the use of which, he says, his patients received much benefit. This instrument has been considerably improved by late practitioners, and is still recommended as very useful.

All the good that can be obtained by compress and bandage, this screw is capable of procuring; but it is also subject to all the same inconveniences, arising from the impossibility of determining exactly the due degree of pressure: for if it be so great as to bring the sides of the upper part of the sac into contact, all communication between it and the puncta will be thereby stopped; if it be too slight, the accumulation will not be prevented; nor does it in either case contribute to the removal of the obstruction in the nasal duct, the primary and original cause of the disease.

If the curative intention was to procure an union of the sides of the facculus, as in the case of parts separated from each other, by the formation of matter or sloughs, and the pressure could be made uniformly and constantly, possibly it might be so managed as to answer a valuable purpose; but as that is not the intention, the pressure, whether made by an instrument, or by a common roller and compress, contributes little or nothing toward a cure.

Besides these means of attempting a cure without incision, the gentlemen of the French academy have tried some others, such as the introduction of a probe into the lower part of the nasal duct within the nose, the injection of a fluid by the same orifice, the passing a seton from the punctum lachrymale superius through the facculus and duct and out at the nostril, there to remain till the cure is completed: and for those purposes they have invented and given figures of a number of probes, syringes, and many other instruments, which, they say, have been very successfully used; though others have not found them to answer the purpose.

When the disease is got beyond the simple state just described, that is, when the parts round about are much or constantly inflamed, or the skin covering the tumour is burst, there is something more to be done if a cure is intended.

In this state, an opening in the upper part of the facculus lachrymalis becomes in general absolutely necessary; and as a wound made by a knife leaves a much less disagreeable scar than that which necessarily follows the bursting of the skin, one being a mere simple division, the other a loss of substance; it will always be found best to anticipate the accident of bursting, by making the opening as soon as the integuments are in such a state as to threaten it.

For the making this incision, authors have been very particular in their directions with regard to its place, manner, and form. They have ordered it to be semilunar, having its concave part toward the eye, and that the point of union of the lids should be exactly opposite to the centre of the incision. This lunated figure was calculated to correspond with the course of the fibres of the orbicular muscle, upon a supposition

Of introducing a probe within the nose.

554

When it is necessary to open the facculus.

that a transverse section of them would produce an inversion of the lower lid, an effect which never follows: all that the surgeon need observe is, to take care to keep the knife at a proper distance from the juncture of the palpebræ, to begin the incision a very little above a line drawn from that juncture toward the nose, and to continue it downward; its form may full as well be straight as any other, and the best instrument to make it with is a small crooked bistury.

If the facculus is already burst, the place of opening is determined; and the orifice may be enlarged with a knife, or dilated.

The incision made, the facculus should be moderately distended, either with dry lint or a bit of prepared sponge; by which means an opportunity will be gained in two or three days of knowing the state of the inside of the sac, and of the ductus nasalis: if the former is neither sloughy nor otherwise diseased, and the obstruction in the latter but slight, it sometimes happens, that, after a free discharge has been made for some days, and the inflammation occasioned by the first operation is gone off, the sac contracts itself, a superficial dressing, with moderate pressure, heals the fore, the lachrymal fluid resumes its wonted course, and the disease disappears.

865
Of dilating
the passage
into the
nose.

If this simple method does not succeed, or from the state of the parts seems unlikely to do so, another must be tried, which the opening already made will enable us to put in practice. The point to be aimed at is, if possible, to render the nasal duct pervious to the lachrymal fluid; and we must endeavour to obtain this end by such means as give the least pain, excite the least inflammation, and leave the parts as near as possible in their natural state; that is, we are to endeavour to dilate the passage from the sac to the nose, by some means which will gradually distend it without destroying its texture, in the same manner as the dilatation of the urethra ought to be effected in the case of strictures, by passing either a probe, or a piece of catgut, or a bougie, gently into it, as far as it will easily go, and repeating it occasionally, until it is got quite through, and the passage is free (A).

When a passage has been once obtained, it should be carefully kept open, either by a piece of catgut, a small bougie, a leaden probe, or something of that sort; and when it is thoroughly established, the fore may be permitted to contract, until it becomes no more than what serves for the introduction of the bougie into the duct; in this state it should be kept open for some time, injecting now and then a little aqua calcis, softened with mell. rosar. through from above into the nose; and when it appears that the passage is so free and so well established that there is good probability of its preserving itself, the orifice in the angle of the eye, by being covered only by a superficial bit of plaster, or pledgit, will contract and close; and if during its closing moderate pressure be used on the facculus, to prevent a fresh accumulation of mucus, it will assist the cure.

866
Of making
an artificial
passage.

The last state of this disorder is that in which the natural passage from the facculus to the nose is so dis-

eased as to be quite obliterated, or in which the bones are sometimes found to be carious. The methods hitherto described have all been calculated to preserve the natural passage, and to derive the lachrymal fluid again through it: in this attempt they are sometimes successful; but when they are not, there is no surgical means left, but to attempt the formation of an artificial one in its stead. The upper and hinder part of the facculus lachrymalis is firmly attached to the os unguis, a small and very thin bone just within the orbit of the eye; which bone is so situated, that, if it be by any means broken through or removed, the two cavities of the nose and of the orbit, communicate with each other; consequently the os unguis forms the partition between the hinder part of the lachrymal bag, and the upper part of the cavity of the nose; and it is by making a breach in this partition that we attempt the formation of an artificial passage for the lachrymal fluid.

To make this opening, many different instruments have been devised, and used; a large probe, an instrument like a common gimblet, a curved trocar, &c. each of which, if dexterously and properly applied, will do the business very well: the one necessary caution is, so to apply whatever instrument is used, that it may pierce through that part of the bone which lies immediately behind the facculus lachrymalis; and not to push up too far into the nose, for fear of injuring the os spongiosum behind, while it breaks its way.

867
Mr Pott's
method.

Mr Pott prefers the curved trocar, which has served his purpose well, and from which he never experienced any inconvenience. In using it, the point should be turned obliquely downward, from the angle of the eye toward the inside of the nose; the accomplishment of the breach will be known by the discharge of blood from the nostril, and of air from the wound upon blowing the nose. The most precise direction in this part of the operation will be of but little use to him who has no idea of the natural structure and disposition of the parts concerned, and who ought therefore to get such information as soon as he can: but whoever is at all acquainted with this matter, or will attend to the situation and connection of the os unguis, knows that this bone is divided into two parts by a perpendicular ridge; that the lachrymal sac is connected to all that part which is anterior to this ridge; and that the posterior part of the bone contributes to form the orbit of the eye, and has little or no connection with the lachrymal sac. The trocar must be applied therefore to that part of the bone which is anterior to the ridge, and consequently behind the lachrymal bag; by the passage of the instrument, all this part of the bone will in all probability be broken, but from which no mischief will ensue.

As soon as the perforation is made, a tent of lint should be introduced, of such size as to fill the aperture, and so long as to pass through it into the cavity of the nose: this should be permitted to remain in two, three, or four days, till the suppurating of the parts renders its extraction easy; and after that a fresh one should be passed every day, until the clean granulating

868
How to
keep it
open.

(A) This caution is very necessary to be observed in the cure of strictures of the urethra; in which case the proper intention is, gradually to dilate the passage, and to procure an increased discharge of mucus from the lacune: this should always be done gently, and by means which give as little pain as possible; whatever irritates or gives pain will certainly do mischief, will add to the obstruction, and increase the dysury.

Practice.

Practice.

lating appearance of the fore makes it probable that the edges of the divided membrane are in the same state. The business now is to prevent the incarnation from closing the orifice, for which purpose the end of the tent may be moistened with spir. vitriol. ten.; or a piece of lunar caustic so inclosed in a quill as to leave little more than the extremity naked, may at each dressing, or every other or every third day, be introduced, by which the granulation will be repressed, and the opening maintained: and when this has been done for some little time, a piece of bougie of proper size, or a leaden canula, may be introduced instead of the tent; and, leaving off all other dressing, the fore may be suffered to contract as much as the bougie will permit, which should be of such length that one extremity of it may lie level with the skin in the centre of the eye, and the other be within the nose.

The longer time the patient can be prevailed upon to wear the bougie, the more likely will be the continuance of the opening; and when it is withdrawn, the external orifice should be covered only by a superficial pledgit or plaster, and suffered to heal under moderate pressure.

There is another method which has been much recommended by some French writers, to prevent the closing of the opening in the os unguis, and which is now generally approved in this country; namely, to introduce a canula either of gold or silver, or lead, into the aperture, and to permit the fore to heal over it, suffering the canula to remain, or to come away by the nose.

Mr Wathen, who has written a treatise on this subject, generally makes use of gold; because most easy to be procured in a state of perfect purity, which is a quality first to be regarded, whatever the metal be: and he prefers this or silver to lead, chiefly on account of their firmer texture, which must render a tube made of either of them less liable to be affected by any pressure it may receive. The tube is somewhat conical, to prevent its descent into the nose; and it is made sufficiently long, to reach from the upper portion of the bony duct, to its aperture below the os spongiosum.

To introduce it more easily, it is furnished with a style, nearly as long as a common probe; the lower end of which is rounded, so as that, passing through the tube, it may exactly fill the aperture at the small end: and it is prevented from passing further, by a shoulder of the same size with the outside of the tube.

The tube is held upon the style by a doubled thread, which passes through a small hole on the one side of its upper or larger aperture, and is continued to a ring at the upper end of the style. By fastening this thread to the ring, the style and tube become one instrument, capable of being introduced and extracted at pleasure, and possessing all the power of a probe.

By means of this, the operator may be enabled to examine the state of the disease, and to judge with the greatest precision of the diameter of the duct, and consequently of the proper size of the tube. For as the duct in persons of different ages, &c. will vary both in the diameter and length, there must on this account be a proportional difference in the tube:

and the operator should therefore be furnished with styles and tubes of several different sizes.

The necessity of paying a close attention to the size of the tube is apparent. For if it be too large, it cannot be introduced; and if too small, it will be liable to slip, if not pass, through the lower aperture of the duct into the nose. If, again, it rises too high, it may press against the sides of the fac, and thus close the orifice through which the tears should pass. If, on the other hand, it comes down too low, it will project beyond the inferior extremity of the duct, and may produce a very troublesome titillation. When the tube is found exactly to fit, the thread, which was passed through the ring at the upper end of the style, being tied in a knot, at about the distance of an inch from the top of the tube, the longer portion of it, above the knot, is to be cut off. By this the style will be disengaged, so that it may be extracted with ease, leaving the tube behind, with the thread hanging out of the wound.

When the tube is fixed, some simple liquor is to be passed by a syringe through it into the nose, as a proof of its being so placed that it will answer the intended purpose. The opening made in the sac might be entirely closed within the space of a few days, if it was not thought proper to leave the thread in. When it has continued there about a week, if the tears absorbed by the puncta are conveyed by the tube to the nose, the thread, which is double, may then be extracted, by cutting one side of it with the scissors, and drawing the other out. The little orifice thro' which the threads passed will be closed in the space of a day. And thus a disorder, which had continued for months, and perhaps years, may be perfectly cured within the short space of a week.

SECT. XVIII. Of Amputation.

In this operation the great end to be aimed at is, the procuring of a handsome stump, in which the bone may not protrude, but be well covered with flesh; so that no excoriation or rawness may be apt to take place, as is too frequently found to be the case after amputation has been performed in the common manner. As long ago as the year 1679, it was proposed by Jacob Young, an English surgeon, in a treatise intitled *Curus Triumphalis ex Terebinthino*, to preserve a flap of flesh and skin, which was to be folded over the bone, and which, uniting to the parts of the wound after amputation, would effectually cover the bone, and prevent the inconveniences abovementioned. No traces of the success of this method, however, can be found till the year 1696; when a Latin dissertation was published upon it by P. Adrians Verduin, an eminent surgeon in Amsterdam. The most sanguine expectations were formed of its success; and it was even thought that the flap would prevent the necessity of tying up the blood-vessels. However, it does not appear that the method as at that time practised, either did or could succeed; and accordingly it was entirely laid aside, till lately that it has been revived with considerable improvements.

§ 1. Of Amputating the Leg.

IN Verduin's method of amputation, the rule was,

to

569
Of introducing a metal canula.

Mr Wathen's directions.

572
Method of
determin-
ing the
quantity of
flesh neces-
sary to be
left for a
flap.

to cut away the fleshy parts to the tendo achillis; and after sawing through the bone, if the flap was too big, it again suffered a second incision. To keep this flap united to the bare bone, he contrived a variety of straps and machines, highly embarrassing to the operator, and painful to the sick. But Mr O'Halloran, having demonstrated that the attempting an union of these parts before suppuration was the true cause of this operation's failing of success, and willing to determine the precise quantity of flesh necessary to be taken off in the flap-operation, found that 15 inches might be considered as a medium standard of the circumference of a man's leg; the diameter of which (supposing it a complete circle) would be about $4\frac{1}{2}$ inches, which appeared to him necessary to be preserved below the amputated part, in order to form a flap sufficient to cover the stump. But as this great length of flesh would make the operation practicable but in a few cases, he began to consider of some conciser means. After sawing some tibiae at the usual place of amputation, and measuring the diameter of the two bones together, he conjectured, that about $3\frac{1}{2}$ inches, might be admitted as a general standard of adults. If, then, an oblique section be made of the skin and muscles, at about three inches, or at most three and an half, below the part to be amputated, and continued in a sloping direction till it reaches the bone, at the place of excision; by a circular incision of the remainder of the flesh and skin at this part, we shall preserve flap enough to cover the ends of the bones. By this means surgeons will be enabled to perform this operation, in every case where amputation becomes necessary; and it will be then found as expeditious as the method of the double incision, and attended with no more pain.

After a trial on a body, he found the flap a little short, on account of the thickness of the gasteroocnemii muscles; but upon repeating his experiment on another body, and having first carefully drawn back as much skin as he could, a flap of $3\frac{1}{2}$ inches answered exactly, allowing for the melting down of the corpus adiposum, and cellular substance of the muscles, by suppuration, as lessening considerably the bulk of flesh, though not the length of the flap. This rule should not be deemed infallible; because, where the limb is extenuated, a less quantity of skin will suffice to cover the extremities of the bones than where the parts are turgid and full. He has since found, that besides the previous drawing up of the skin, if in the circular tour care is taken to save some skin in the anterior part of the leg, which is easily done by drawing it back during the incision, a flap of three inches will certainly answer. This operation he performed three times successfully in the course of eight months, and never measured the quantity of flesh he intended to preserve, but with the eye; however, in a week after each operation, he was curious enough to measure the particular flaps. The first measured $3\frac{1}{2}$ inches without, from the extremity of the flap to the place of the circular incision; and $2\frac{1}{2}$ from the internal edge of the flap to the bone; and this flap was found sufficient to cover the extremity of the stump, though a good-sized leg; and that the circumference of it measured 24 inches. In the second case, the flap measured from without, three inches; and internally, not quite two. This woman's leg was smaller than the first patient's,

but both bones were rather larger and much more firm. The periphery of this stump was twelve inches. In the third instance, the leg was burnt so high up, that no greater flap could be allowed than two inches and one-fourth, and from within it measured $1\frac{1}{2}$ inches; and yet this stump was also completely covered with a good cushion of flesh and skin. The limb was greatly extenuated, and the circumference of the stump was not quite ten inches. Upon the whole, then, he conjectured that the difference between 3 and $3\frac{1}{2}$ inches of a flap, will take in most legs; i. e. in adults, that it should be seldom under 3, nor ever exceed $3\frac{1}{2}$ inches.

These necessary details premised, where the necessity of taking off a leg is manifest, let the hair be shaved off from the knee to where the limb is to be taken off, which will save the patient a good deal of trouble in the dressings. The skin should then be drawn up pretty tight; and let a small band moderately rolled up, and sewed from its outside folds to the centre of an open roller, of about two inches broad and a yard long, be placed in the ham, over the artery; and with the open one going round the knee, let it be thus firmly secured. If one side of the open band is perforated, so as to make it a kind of uniting band, it will roll smoother. Then with Petit's or the common tourniquet, let the artery be sufficiently compressed. On this occasion Mr O'Halloran prefers the common one; because, by its uniform pressure round the limb, less blood is lost than in the ordinary way. The difference, nevertheless, is not of so much consequence as to give one an absolute preference to the other: the choice, therefore, may be safely left to the option of the surgeon. The patient should be placed on a chair, or low table, of about two feet high, as the leg must have some degree of elevation. All the apparatus being properly disposed, which consist of a straight edged knife, with the blade as long as that of the common cateline, and pointed at its extremity, the common amputating knife, saw, and a few needles armed with flat threads, waxed, of different sizes. Let the leg be elevated about a foot higher than if in an horizontal posture; and with strong tape of about an inch broad, let it be bound round pretty firm at the intended place of excision; and if at this time he lies in a reclining posture, the raising the leg will be the more easy.

Mark with a pen the traces where you are to commence your incision, which should be, in adults at least, three inches from where the bone is to be sawed. Then with the straight incision-knife, make an oblique section from this point almost or quite to the bone, ending at your tape: then with this same, or the common amputating knife, let the circular incision of the remainder of the flesh be expeditiously performed. To do this first part of the operation with greater ease to yourself and advantage to the patient, you must be careful, if the left leg be the part diseased, to place yourself between his legs; and if the right, to be outside the limb. The reason of these situations is very obvious; for you cannot with the right-hand command an exact sight, or commence your operation dexterously, but in these postures. This done, apply a split cloth, the two tails of which should cross over the tibia, and with the single one draw back the flap. Though some operators do not approve of the split cloth in the com-

572
Method of
performing
the opera-
tion.

mon method, yet here it is essentially necessary: for this purpose the tape should be first removed. Any little undivided flesh may be now separated by the cateline; the peritœum divided round about, and scraped upwards, agreeable to the advice of professor Monroe; and the ligamentum interosseum divided. The next thing to be done is to saw the bones; but whatever be your position in dividing the soft parts, you must be always between the legs to cut away the bones. As soon as you have marked the traces of the saw on the tibia, run it along both bones, very light and nimble; and continue this manœuvre till the bones are divided. By this means the teeth of the saw will not be entangled in the bones, nor you often obstructed in your motion; but the divided bones will be smooth, and the operation expeditious.

573
Of tying up
the blood-
vessels.

The limb being taken off, the tourniquet must be relaxed, and the tibialis anticus, posticus, and interosseus arteries, carefully taken up. Where the flesh was thin, and not very firm, Mr O'Halloran has sometimes made a ligature round the bone in which the artery was included: but if you use, instead of the ligature of the vessels, the agaric or lycoperdon, which, our author thinks, may be safely depended on in the leg and fore-arm, you must be careful that the fungus does firmly adhere to the vessels before you dress up the stump; as also that it be not removed during the last period. As for the vessels that spread themselves on the gastrocnemii and solæus muscles in this operation, the taking them up becomes necessary. The blood being carefully mastered, which you will know by relaxing the tourniquet for some time, and no blood spurting out, you are then to dress the stump thus. Let the tibia be covered with a pledgit of dry lint, and the rest of the stump with soft lint, loose, and strewed with fine flour. In the thigh and arm, besides the future, he generally applies some lycoperdon to the extremities of the principal vessels; the same may be also done in the present case, if the ligature has been used. He particularly recommends it to the space between the tibia and fibula; because it sometimes happens that the interosseus artery shrinks between the bones; and though no appearance of an hæmorrhage at present happens, yet in a few hours it may return. The possibility of this accident justifies the precaution. The flap is likewise to be dressed with soft loose lint, and a cloth cut in form of a double T, and covered with adhesive plaster, is to cover the dressings. Its figure is thus:

The long one is to surround the stump above the amputated part, whilst the tails, by crossing the flap, press it against the stump, and make all the dressings the more compact. This done, an hog's bladder moistened and notched is to inclose the stump; but previous to this an handful of lint is to be applied between the outside of the flap and the bladder: press this last to the stump; and the notches covering each other above make the whole dressings smooth, and the pressure soft, and such as is best calculated to prevent an hæmorrhage. Let a cross compress, moistened,

cover the bladder; and then with a band, of between eight and nine yards long, and near three inches broad, rolled up to two heads, secure your dressings thus:

After removing the tourniquet and other bands used antecedent to the operation, an handful of soft lint should be applied to the ham; which, in the circulations of the band here, greatly restrains the violence of the blood; for as this is the most troublesome and alarming symptom, and the most reproachful to the surgeon, all these precautions are justifiable. With one of the heads of your band make three circulars above the knee moderately tight; then with the same descend, and make two or three turns below the knee, rather smooth than tight; and then mount obliquely till you get above the knee, and here make a circular turn. Let the other head of the band go straight down from the posterior and inferior part of the thigh over the flap, and above the knee anteriorly; which will become here secured by a circular turn of the other head over it. Let the other head again cross the stump and flap from the inside of the thigh, and ascend at its outside above the knee, and here be again secured by a fresh circular turn of the other head. Cross over the stump again between these folds, so as to form on the flap a kind of star of six points; and this fold becomes also secure by a new turn of the other. Let the remainder of both bands be then disposed of round the thigh at pleasure, or cut off.

575

The stump being dressed, let the patient be laid on his bed, and a pillow put under the thigh, so as to raise that part. Let the patient be kept to a proper diet: but in this point it is impossible to fix any criterion; for regard must always be had to the patient's usual manner of living, what is high diet to one being insufficient to preserve the life of another. And on this single point the success of many a cure plainly depends. In general, young people of plethoric habits should be kept low; those advanced in years, or whose constitutions are otherwise impaired, should live freer. Some bleed on the commencement of the fever; but this ought to be avoided, except the fever is high, or the subject full of blood; because without a fever there can be no suppuration, of course no tendency to recovery. In general, the first opening of the fore should not be for four or five days, according to the season or symptoms. This should be done, by first softening the dressings in warm water, and removing only as much of the lint as comes off loose and easy. Let the whole part be then covered with pledgits, armed with proper ointment, and secured by the double T plaster, with the compress and bandage already described. The flap and the stump, at every dressing, are to be regarded as distinct forces, and separately dressed. If the discharge is small, it may be promoted by stuping the stump with sponges pressed out of very hot water, by the common digestive, and the like. If abundant, it may be lessened by dosils of lint wet in brandy or tincture of myrrh, or by dry lint alone, which is an excellent absorbent: the bark, in substance, will also greatly restrain it; often a pill or two of calomel. In general, an abundant suppuration will promote a speedy coalition; whereas, when slow, it will be more tedious.

About the 12th day, then, that is, when inflammation is entirely passed, and suppuration effectually

esta-

Practice.

established, the bare flap may be turned up against the naked stump, and so be secured by plaster, compression, and bandage. Instead of the bandage already described, our author on this occasion uses one composed of a strip of strong cloth to go round the knee; and to the centre of this is fixed another, which, crossing from under the ham, the stump is secured to the circular above the knee by means of four or five pieces of tape attached to this last. The fore should not be opened for at least two days after this, and the dressings taken off with great caution. He often bathed this part very hot; and though the flap should in part separate, yet must it again and again be returned until the parts firmly unite. The little sore which the flap does not cover should be dressed with lint and brandy. Soon after the union of the flap and stump, the former sometimes inflames; but a relaxing fluke, and a poultice of flummery, soon removes this. At every dressing of the remaining little sore of the flesh, the stump may be bathed in bran and water hot, which will greatly accelerate healing. Though after 15 or 16 days the cure may be finished by any common nurse, yet do the parts remain tender for some days longer. By the dissection of one of his patients, who died many months after this operation of a malignant small-pox, our author found it was occasioned by the extremities of the bones not being completely healed: so that what he then thought a disadvantage to this operation, appears now to be one of its greatest excellencies; namely, that the bones should be fairly covered by a firm periosteum; which at the same time accounted for this phenomenon.

§ 2. Of amputating the Thigh.

To attempt this operation, by preserving a flap of flesh in the posterior and inferior part of the thigh, must leave so large a flesh-wound, and so great a quantity of muscular flesh bare, as to require a very great length of time to bring on a firm union of the divided parts: besides, the fever, and great discharge from so large a surface, may alone endanger the patient's life. Mr O'Halloran, after a variety of trials, concluded, that a flap of flesh and skin preserved in the anterior part of the thigh, must answer our most sanguine expectations: for the quantity of flesh here is not much, the skin, corpus adiposum, and rectus muscle, being only interested in the incision; of consequence the wound not considerable, and the flap not required very large. Our author attempted to determine, on a dead body, the quantity of flap necessary to be preserved in this manner. The circumference of the thigh, at four inches from the inferior part of the rotula, measured eighteen inches. Here he drew up the flesh, and bound it by a small band. He then began a flap-incision on the rotula, bringing it up to the circular band, and here sawed through the bone, having first cut through all the intervening flesh. The preserved flap measured three inches externally, and two and an half from the circular incision of the flesh to its internal extremity. The diameter of the femur, in its lowest axis, or nearly from side to side, was exactly an inch and one-tenth; and yet this flap, besides completely covering the bone, extended an half inch beyond it. By this plain and simple experiment, it appears, that the flap-opera-

tion in the thigh, by making your incision in its anterior part, becomes less complex, less painful, and even more expeditious in its cure, than the same operation in the leg. After determining on the precise place on which the limb is to be taken off, care must be taken to have the blood-vessels mastered in the operation, either by Petit's or the common tourniquet, as in the usual manner: then let the flesh and skin be tightly drawn up from the knee, and so secured above the place of election by a circular tape or band. Mr Gooch proposes a kind of thick circular cushion to serve instead of this band, to direct the knife exactly in the circular tour; but Mr O'Halloran thinks that a thick tape will answer this purpose every bit as well, as this operation is mostly exactly even, and that the cushion rather hinders the direction of the knife from the eye. With a straight knife, such as has been described in taking off the leg, commence your flap-incision at about three inches more anteriorly than where the bone is to be sawed through, supposing an adult, and so in proportion to the age and size of the limb. Let this incision be continued in an oblique direction till you reach the bone at the circular tape; then with the same, or a common amputating knife, make your circular sweep, commencing from the side of the flap and directly to the bone; observing here, as in the leg, to place yourself outside the body in taking off the right thigh, and between the legs in removing the left. But then there is no necessity here, as in the leg, of change of place in sawing the bone; because, as it is but one, wherever you place yourself to cut off the soft parts, there you may stay to finish the operation.

As soon as the circular incision is completed, the tape should be removed and the split cloth cross the divided parts, in order to draw up the skin and muscles, the single tail covering the flap; and as soon as the periosteum is separated, &c. let the bone be sawed. The femoral artery should be secured as already directed; and besides this ligature, let some agaric or lycoperdon be applied: and any other considerable branches of vessels may be taken up or stopp'd by the above funguses. Let the surface of the sore be covered with loose unformed lint strewn with flour, and the flap laid over this dressing covered by a double T plaster; an handful of lint outside this, gently pressed against the flap by an hog's bladder, moistened and notched at its orifice; and the whole covered by a cross compress. Let soft lint, tow, or a linen compress, cover the direction of the artery; and secure all these dressings on by a band about three inches broad, and twelve yards long, rolled up in two even heads. Apply a large handful of loose lint or soft tow over the femoral artery near the groin; and after making a couple of circulars about this part, moderately tight, so as to break in some measure the force of the circulating fluid, let the bands cross round the body. Fix a piece of strong tape, about an inch or more broad, and a yard long, along the inside of the amputated thigh, one end of which is to be secured to the band that went round the body, and the other to hang loose over the stump: let a similar piece of tape be in like manner fixed to the outside of the thigh: then, with one of the heads of your bandages, make three or four circulars round the thigh over these tapes, gently descending;

576

flap neces-
sary to be
preserved in
amputating
the thigh.

577
Of dressing
the stump.

scending; and with the other head cros directly over the anterior part of the thigh and stump, and ascend posteriorly: a couple of circulars of the other head, gently ascending, will secure it smooth and firm. Descend again over the inside of the thigh, cros the stump, and mount with your first band outside the thigh; and here another circular or two makes this second turn firm. Between the anterior and lateral turns of the band you must bring down your roller cros the stump, and ascend in the opposite direction: and here, again, a couple of circulars of the other roller will make all firm. Between the posterior and lateral parts of the band you must make a fourth turn over the stump, and secure it by another circular, and finish both heads by circulars or spiral turns round the stump; or if too long, they may be cut off. Though the stump be now apparently well bound, yet, by reason of the form of the thigh, the bands may be apt to loosen, or even drop off: to prevent this, let the tapes already mentioned be turned up at their loose extremities; the inside one to cros over the inside of the thigh, and, as it ascends, to be here and there secured by pins to the circulars, and to part of the band that went round the body; and in like manner the outside tape. By this means the circular turns, which only could loosen, will be smoothly retained in their different places, and the whole bandaging convenient, firm, and even. The bandaging, however, should be but moderately tight, as the swelling of the stump will soon make them sufficiently distended.

In winter, the stump should not be opened before the fifth, or even sixth day; nor in summer sooner than the fourth: the bone should be dressed with dry lint, or lint wet in brandy, and the soft parts with the common digelive; taking care to remove no more of the old dressings than what are loose. When suppuration is well established, the stump and flap may be dressed with dry lint, as the soft digelives at this time are apt to encourage exuberant or proud flesh. If, nevertheless, such should rise on the flap, it may be now and then sprinkled with red precipitate; but the surgeon need never be uneasy at attempting an union of the flap and stump at such time. About the 12th or 13th day, and not sooner, should the flap and stump be brought into perfect union: before this they are to be treated as distinct fores, and preserved in such situation by a bandage something like what has been recommended for the leg. But whereas that was secured above the knee, to make this a fixed point, the straps must go round the body, and the body of the band lie on the anterior part of the stump, in order gently to bring the flap and stump into an exact union. This first dressing is not to be opened for three days; and every other rule recommended in the leg is here exactly to be followed. If, in the suppurative state, the fore should have an unusual degree of pain and sensibility, the parts may be often bathed in milk and water; the sick let blood; and even opium, alone or mixed with digelives, may be successfully applied to the parts.

§ 3. Of amputating the Arm.

In amputating the thigh, we have, for very obvious reasons, chose to take the flap from its anterior part, as being a less considerable wound, having less of sub-

stance, and of course sooner covering the bone, the principal object of all. For precisely the same reasons, in taking off the arm, the flap of flesh should be taken from its posterior part, as being less fleshy, and nearer the bone: here a flap of flesh, from two and half to three inches, will be certainly sufficient to cover the bone. The bandaging here must be pretty nearly the same as in the thigh; though, as the arm is almost cylindrical, some may think it unnecessary to cros the band round the body, as it might be apt to heat and oppress the patient. But if this should be thought proper to be dispensed with, a flat tape should from the neck hang down each side of the arm, the bandaging to be performed over it, and the two extremities of it turned back, pinned to the circulars, and so firmly secured to the neck-band. The union should be attempted about the eleventh day.

§ 4. Of amputating the Fore-arm.

To take off the fore-arm, we must look for the flap in its external part, as having less to cut through; but above all, as by this means you avoid bringing in that groupe of tendons which cover the inside of the fore-arm. Here from an inch and an half to two inches will be undoubtedly sufficient to cover the bones; but then in the incision you must comprehend the full breadth of the flesh and skin on the back of the fore-arm. The dressings and bandaging will be easily comprehended from what has been already said; and about the tenth day you may attempt an union of parts.

SECT. XIX. The Method of opening a dead Body.

SURGEONS are often called on this occasion, in order to investigate the cause and seat of diseases and death, either by the relations of the deceased, or the magistrates, to whom report is to be made; therefore, at the time of performing this operation, minutes should be taken of what is observed. The instruments, and all things necessary, should be disposed in order, as for any other operation; as knives, a razor, a great and small saw, scissars straight and curved, elevators, needles threaded, sponges, tow, saw-dust or bran, basons with water, towels, and receivers for the viscera when they are to be taken out of their cavities; and should the body have undergone any degree of putrefaction making it offensive, it will be right to have a mixture of lavender-water and vinegar, or some such thing, to sprinkle it with, &c. The body is to be laid upon a suitable table, advantageously placed for the light, having a cloth thrown over the parts which decency demands should be concealed, especially in females.

When it is intended only to inspect the abdomen and its contents, a longitudinal incision from the xiphoid cartilage to the os pubis, intersected by a transverse one at the navel, will give a fair opportunity of answering these purposes, when the angles are reversed. Should it be required to examine all the three cavities, and the parts contained in them, we are to begin by opening the head, making an incision quite cros to the bone, from ear to ear; which section is preferable to the crucial, commonly made on this occasion: then the scalp may be easily dissected from the skull, and turned down over the face,

Practice.

and towards the neck, giving room for the saw. The head must be held very readily by an assistant during the sawing, which should be begun on the middle of the frontal, proceeding to each temporal bone, and so to finish the circle upon the middle of the occipital bone; which may generally be done conveniently enough, by raising the head and inclining it forward, after having proceeded as far as this bone; or the body may then be turned prone, should that posture be found more convenient, to complete the circle. The cap of the skull is then to be raised with the elevator, occasionally cutting the adhesions of the dura mater: after this the encephalon is to be removed, carefully separating the other attachments of the membrane.

In order to bring the thorax and abdomen, with the parts contained in these cavities, under one view, an incision is to be made on each side the sternum, in the course of the cartilages of the ribs which are annexed to it; dissecting from thence the muscles with the teguments, the space of two or three inches towards the spine; then cutting through the cartilages, which will be seen, and easily divided with a knife a little curved near the point; then the incisions are to be continued from the sternum through the abdominal cavity, in an oblique direction, to each ilion or inguen; after which the clavicles are to be separated from the sternum, or this bone divided at its superior cartilaginous junction, with a strong knife, dissecting it from the mediastinum, and turning it downwards with the muscles, &c. of the abdomen. This is the most eligible manner of opening these cavities, and gives an opportunity of sewing them up, with a better appearance for any person's view afterwards. That kind of stitch called by sempstresses the *herring-bone* or *flat seam*, has a very pretty and neat effect upon these occasions.

If it is proposed to take out the thoracic and abdominal viscera together, for further examination, the diaphragm is first to be cut down to the spine on both sides; then, to avoid being incommoded with blood, &c. two very strong ligatures are to be passed round the œsophagus and large blood-vessels, in which the trachea may be included; tying them strait, and then dividing these parts between the ligatures: the same measures are to be taken in respect to the inferior vessels, upon the lumbar region, a little above the bifurcation of the aorta, including the vena cava; and also upon the rectum. After having observed these precautions, the viscera, with the diaphragm, are to be removed, by a wary dissection, all the way close to the spine; and gently drawing them at the same time, will greatly facilitate the separation.

When the thoracic and abdominal viscera are to be taken out separately, in the first case ligatures must be made as have been described upon the vessels, &c. just above the diaphragm, and in the other just below it, and upon the rectum.

Should we be called upon to perform this office when the body is become very putrid, it will be absolutely necessary to have such parts of it well washed with warm vinegar and brandy, and then sprinkled with lavender-water or some such odoriferous antiputrescent liquor, before the examination, in order to correct the stench, and defend us against the noxious

quality of the effluvia: a precaution, the neglect of which may be attended with very direful effects, and of which we have instances.

Practice.

SECT. XX. Of Embalming dead Bodies.

In the early ages of the world, the practice of embalming dead bodies was very common, particularly among the Egyptians; but it has long been disused in almost all countries, except for great personages. See EMBALMING. The following directions are taken from Mr Gooch, to whom they were communicated by a person of great character, and well acquainted with the modern practice of embalming in this kingdom.

After evisceration, as has been directed in opening a dead body, and continuing the incision farther upwards, even into the mouth, and, if practicable, without cutting the skin of the neck, all the cavities are to be well cleaned, and the humidity sucked up with sponges, then washed with *tinct. myrrhe*, and filled with a species, compounded of fragrant herbs, aromatic drugs, and gums reduced to powder not very fine, first restoring the heart to its former residence, after having opened its ventricles, cleaned and washed them with the tincture, stuffed them with the species, and sewed them up; and then the cavities are to be stitched very close with the glover's or spiral suture. Large and deep incisions are also to be made in all the most fleshy parts, cleaning and washing them with the tincture in the same manner, filling them with the antiseptic species, and stitching them up. Then the head, trunk, and limbs, are to be perfectly well covered with cerecloth; putting a piece under the chin, to be secured by sewing on the top of the head, after having well adjusted the cap of the skull, sewed the scalp together, and cleaned the mouth, as has been directed for the other parts, and putting in some of the species. The cerecloth is to be prepared, according to art, with a composition made of wax, rosin, storax, and painter's drying oil. After the application of the cerecloth, with great care and exactness, cut into suitable pieces, according to the respective parts, and closing them well every where; the face being close shaved, is to be covered with some of the above composition melted, and laid on with a brush of a proper degree of heat, and of a moderate thickness; which may have a faint flesh-colour given it with vermilion; and when it is grown cold and stiff upon this part, it may belightly struck over with hard varnish; or this varnish, applied thick, may here serve the purpose alone. A cap is to be well adapted to the head, falling down upon the neck, and to be sewed under the chin, making a few circular turns about the neck with a roller of a fit breadth. All the rest of the corpse is to be inclosed in a sheet, to be artfully cut, and sewed on very close and smooth, with the finest tape, and the flat seam mentioned in the preceding section; over which an appropriate dress is to be put, as the relations or friends think fit to direct and appoint, and then laid into the coffin, which should be in readiness: but when it is some great personage, who is to lie in state for public view before the funeral rites are solemnized, the dress must be appropriated to his dignity and character. The brain and other viscera are to be put with some of the species into a leaden box. Sometimes

551

times the heart, prepared as has been directed, to preserve it from putrefaction, is deposited in an urn by itself.

EXPLANATION of Plates CCLXXVIII. CCLXXIX. CCLXXX. CCLXXXI. CCLXXXII.

FIG. 1. A, A director by which to guide the knife in the opening of abscesses that are burst of themselves, or first punctured with a lancet. This instrument should be made either of steel, silver, or iron; but so tempered, that it may be bent and accommodated to the direction of the cavity. It is usually made quite straight; but that form prevents the operator from holding it firmly while he is cutting. The manner of using it is, by passing the thumb through the ring, and supporting it with the fore-finger, while the straight-edged knife is to slide along the groove with its edge upwards, towards the extremity of the abscess.

B, The straight-edged knife, proper for opening abscesses with the assistance of a director; but which, in few other respects, is preferable to the round-edged knife.

C, A crooked needle, with its convex and concave sides sharp: this is used only in the future of the tendon, and is made thin, that but few of the fibres of so slender a body as a tendon may be injured in the passing of it. This needle is large enough for stitching the tendo achillis.

D, The largest crooked needle necessary for the tying of any vessels, and should be used with a ligature of the size it is threaded with in taking up the spermatic vessels in castration, or the femoral and humeral arteries in amputation. This needle may also be used in sewing up deep wounds.

E, A crooked needle and ligature of the most useful size, being not much too little for the largest vessels, nor a great deal too big for the smallest; and therefore, in the taking up of the greatest number of vessels in an amputation, is the proper needle to be employed. This needle also is of a convenient size for sewing up moist wounds.

F, A small crooked needle and ligature for taking up the lesser arteries, such as those of the scalp, and those of the skin that are wounded in opening abscesses.

Great care should be taken by the makers of these needles to give them a due temper: for if they are too soft, the force sometimes exerted to carry them through the flesh, will bend them; if they are too brittle, they snap; both which accidents may happen to be terrible inconveniences, if the surgeon be not provided with a sufficient number of them. It is of great importance also to give them the form of part of a circle, which makes them pass much more readily round any vessel, than if they were made partly of a circle, and partly of a straight line; and in taking up vessels at the bottom of a deep wound is absolutely necessary, it being impracticable to turn the needle with a straight handle, and bring it round the vessel when in that situation. The convex surface of the needle is flat, and its two edges are sharp. Its concave side is composed of two surfaces, rising from the edges of the needle, and meeting in a ridge or eminence, so that the needle has three sides. The best materials for making ligatures, are the flaxen thread

that shoe-makers use; which is sufficiently strong when four, six, or eight of the threads are twisted together and waxed; and is not so apt to cut the vessels as threads that are more finely spun.

G, A straight needle, such as gloves use, with a three-edged point, useful in the uninterrupted future, in the future of tendons where the crooked one C is not preferred, and in sewing up dead bodies, and is rather more handy for taking up the vessels of the scalp.

Fig. 2. A, The round-edged knife, of a convenient size for almost all operations where a knife is used: the make of it will be better understood by the figure than any other description; only it may be remarked, that the handle is made of a light wood, as indeed the handles of all instruments should be, that the resistance to the blades may be better felt by the surgeon.

B, A pair of probe-scissors, which require nothing very particular in their form, but that the lower blade should be made as small as possible, provided it be strong and has a good edge; because, being chiefly used in fistulas *in ano*, the introduction of a thick blade into the sinus, which is generally narrow, would be very painful to the patient.

C, The crooked knife with the point blunted, used in the operation of the bubonocoele.

Fig. 3. A, A trocar of the most convenient size for emptying the abdomen when the water is not gelatinous. It is here represented with the perforator in the canula, just as it is placed when we perform the operation.

B, The canula of a large trocar, recommended in cases where the water is gelatinous.

C, The perforator of the large trocar.

Fig. 4. A, A sound used in searching for the stone. The size represented here is but a little too large for the youngest children, and may be used upon boys till they are thirteen or fourteen years of age: a larger should be employed between that age and adulthood, when one of about ten inches, in a right line from the handle to the extremity, is proper. This should be made of steel, and its extremity be round and smooth.

B, A staff fit for the operation on boys from eight to fourteen years of age. The staff for a man must be of the size of the sound already described.

C, A staff something too big for the smallest children, but may be used upon boys from about four years of age to eight.

The staff has a groove on its convex side, which first serves as a direction where to cut, and afterwards, receiving the beak of the gorget, guides it readily to the bladder. Care should be taken, in making the groove, that the edges of it be smoothed down, so that they cannot wound in passing through the urethra. The extremity should also be open; otherwise it will be sometimes difficult to withdraw the staff when the gorget is introduced, and presses against the end of it.

These instruments are usually made with a greater bending than here represented; but this shape is more like to that of the urethra, and rather more advantageous for making the incision.

D, The yoke; an instrument to be worn by men with an incontinence of urine. It is made with iron,

but for use must be covered with velvet. It moves upon a joint at one end; and is fastened at the other by catches at different distances placed on a spring. It must be accommodated to the size of the penis, and be taken off whenever the patient finds an inclination to make water. This instrument is exceedingly useful, because it always answers the purpose, and seldom galls the part after a few days wearing.

Fig. 5. A, A small catheter made of silver. This instrument is hollow, and serves to draw off the urine when under a suppression. It is also used in the high operation to fill the bladder with water. Near its extremity are two orifices, through which the water passes into its cavity. Care should be taken that the edges of these orifices are quite smooth.

B, The knife used in cutting for the stone: it is the same already described; but it is not improper to repeat the figure with the alteration of a quantity of tow twisted round it, which makes it easier to hold when we perform the lateral operation, and turn the edge upwards to wound the prostate gland.

C, A female catheter, differing from the male catheter, it being almost straight, and something larger.

D, A silver-wire to pass into either catheter, for the removing any grumous blood or matter that clogs them up.

Fig. 6. A, The gorget used upon men in the lateral operation.

B, The gorget used upon children under five years of age in the lateral operation.

A gorget between the sizes of these two will be fit for boys from five years of age to fifteen or sixteen.

These instruments are hollow for the passage of the forceps into the bladder; and their handles lie slanting, that they may the more readily be carried thro' the wound of the prostate, which is made obliquely on the left side of it. The beak at the extremity of the gorget must be smaller than the groove of the staff which is cut upon, because it is to be received in the groove. Care should be taken that the edges of the gorget near the beak are not sharp, lest, instead of dilating the wound as it ought, it should only cut on each side when introduced; in which case, it would be difficult to carry the forceps into the bladder.

C, A gorget, with its handle exactly in the middle. This shaped instrument is used in the old way. All the gorgets should be made of steel.

Fig. 7. A, The forceps for extracting the stone. These are represented a little open, that the teeth may be better seen within-side.

This instrument must be of different sizes for different ages and stones, from the length of four inches to one of near a foot long; but the forceps of about eight inches long will be found most generally useful. The number necessary to be furnished with will be four or five.

Great care should be taken by the makers of this instrument that it move easily upon the rivet; that the extremity of the chops do not meet when they are shut; and particularly that the teeth be not too large, lest, in entering deep into the stone, they should break it. It is of consequence also that the teeth do not reach farther towards the joint than here represented; because a small stone, when received into that part,

being held fast there, would dilate the forceps excessively, and make the extraction difficult; on which account, the inside of the blades near the joint should be smooth, that the stone may slip towards the teeth.

B, A director made of steel, used for the direction of the gorget, in the extraction of the stone from women.

C, A scoop to take away the stone when it is broken into small pieces like sand. This instrument is made of steel.

Fig. 8. A, The perforator, commonly called the *perforating trepan*. With this instrument an orifice is usually made for the reception of the pin on the centre of the piece of bone that is to be taken away in the operation of trepanning; though, if the pin be very sharp, and project but little beyond the teeth of the saw, as in that marked with the letter B, the perforator would be needless; but as the point of the pin presently grows blunt with use, and in that case it is difficult to fix the saw, it is advisable to have this instrument in readiness. It is also handy for boring into the substance of the bones, in order to promote a granulation of flesh on their surfaces. When it is made use of, it must be received and fastened in the handle C.

B, The crown or saw of the trepan, with the pin appearing just beyond the extremities of the teeth. The shape of this saw is cylindrical.

C, The handle of the foregoing instrument, called the *trephine*; which is much preferable to the trepan (an instrument like a wimble used by joiners), because of the great convenience of holding it, and leaning on one side or other of the saw, as we find it necessary: The trepan, however, though allowed to be unhandy, is the instrument most used by surgeons in other parts of Europe, upon the supposition of its working quicker than the trephine.

The trephine here represented is of such a shape as to make it a convenient elevator; for which purpose the extremities of it are made rough.

D, A key to take out the pin E, when the saw has made an impression deep enough to be worked without the help of it.

Fig. 9. A, A convenient forceps to take out the circular piece of bone, when it does not stick to the saw: the contrivance by which they readily lay hold of it, is to make the extremities that are to grasp it with an arch of the same circle as the saw is made. Upon one of the handles there is added a little elevator, to lift up any small splinter of bone.

B, A lenticular: the fore-part of its blade is sharp, in order to scrape the lower edge of the orifice of the cranium, in case any splinters should remain after the operation; and the button at its extremity receives the dust, that it may not fall on the brain; but there is seldom any occasion for this instrument.

C, A rugine or raspator, for scraping bones in order to promote granulations of flesh. The handles of these two last instruments are wood; whereas every part of the others should be made of steel.

Fig. 10. A, The couching needle; the broad part of which towards the point is flat on one side; but on the other is a little convex, to give it more substance and strength.

The handle of this instrument is white ivory, inlaid with a streak of black in that part of it lying even with

Practice. with the convex surface of the blade: The meaning of which is, that by holding the handle with the streak upwards, we may be guided to depress the membrane of a milky cataract with the flat surface, though the substance of the cataract swimming in the eye obscures the needle, and prevents its being directed in a proper position by the sight.

B, A speculum oculi, which is made to open or shut by an iron button sliding along a slit in the handle. This instrument is composed of one piece of steel, in such a manner that it would fly open by its elasticity, if the two branches of the handle were not confined by the button. The circle of it should be covered with velvet, to make it lie softer on the eye-lids.

C, The knife for cutting the iris; the blade of which has two edges, resembling a lancet, which are more advantageous than one only, in cutting the cornea for the extraction of the cataract.

Fig. 11. A, the eye, with the skin of the eye-lids denuded, in order to show the orbicularis muscle: the white streak running from the inner angle of the eye towards the nose, is the tendon of the orbicularis muscle. At a little distance from the internal angle, on the edge of the eye-lids, may be observed two black spots, which are the orifices of the lachrymal channels, and called the *puncta lachrymalia*.

B, the exact dimension of the lachrymal channels and bag; the prickled line represents the edge of the orbit.

C, A small incision knife, more handy than a larger for opening the bag.

D, The perforator to destroy the os unguis, if ever it should happen to be necessary.

E, An iron instrument made thin and pliable, to set even on the forehead, and for use covered with velvet: the holes at the three extremities receive two pieces of ribband, by which it is fastened on the forehead: the button at the end of the screw is to be placed on the sacus lachrymalis, and the screw to be twisted till the button makes a considerable pressure on the bag: the button should be covered with velvet, and a little compress of plaster be laid on the bag before it is applied, to prevent the skin from being galled by the pressure. The little branch of iron which receives the screw must be soft enough to admit of bending, otherwise it will be difficult to place the button exactly on the bag. This instrument is for the left eye only; it should be worn night and day in the beginning of a fistula, and after a fistula has been healed by incision; but as the success depends upon the exact situation of the button upon the bag, it should be carefully looked after.

Fig. 12. A, The bent probe used in extirpating the tonsils, fixed in a handle, with the ligature made of the same thread as the ligatures for tying the blood-vessels.

B, The iron instrument for tying the tonsils.

This instrument is also of great service in extirpating, by ligature, a species of scirrhus that sometimes grows from the neck or cavity of the uterus.

C, The needle with the eye towards the point, for passing the ligature through the tonsil, when the basis is larger than the extremity.

D, A canula made of silver to be used in the empyema.

E, A canula to be used in bronchotomy.

To keep the canulas in their place, small ribbands may be passed through the rings of them, and carried round the body and neck; or they may be held by a ligature run through, and fastened to a hole cut in a piece of sticking-plaster, which is to be laid on each side of them.

Fig. 13. A, The instrument called the *probe razer* to cut the mastoideus muscle in the wry neck; it is sharp only about half its length at that end where the blade is broad.

B, The two pins with the twisted suture, used in the bare-lip.

C, The polypus forceps, with one of the rings open for the reception of the thumb, which would be cramped in pulling the forceps with much force, if it were received in the same sort of ring as in the other handle.

Fig. 14. A, The figure of the amputating knife. The length of the blade and handle should be about thirteen inches.

B, The figure of the saw used in amputating the limbs. The length of the handle and saw should be about seventeen inches.

Fig. 15. The form of the tenaculum used for pulling out bleeding vessels to be tied up.

Fig. 16. and 17. Two needles of a different form from those in ordinary use, recommended by Mr. Bell as the most convenient, particularly in deep wounds.

Fig. 18. The instrument named *porte-aiguille*, for passing through the pins in making the twisted suture.

A, The handles.

B, A groove for receiving the pins used in the suture.

Fig. 19. A flat needle, sometimes useful in stitching blood-vessels that lie between contiguous bones.

Fig. 20. An improved tourniquet by Mr. Bell. The manner of using it described p. 8415.

Fig. 21. An improved trocar by Mr. André, for the purposes of tapping for the ascites or hydrocele. The roundness of its point makes it pierce more easily than the common one, which is triangular. That the instrument may be easily withdrawn after the perforation is made, the canula (fig. 22.) is composed of two pieces screwed together; by unloosening which the instrument will easily dilate them, and they will close by the pressure of the surrounding flesh, so as to afford a passage for the liquid to be drawn off.

Fig. 23. Mr. Bell's trocar for evacuating the contents of an encysted hydrocele. By the flatness of its form, and its point being of the lancet kind, this instrument penetrates the cyst with great ease; and can thereby be used with more safety than the ordinary form of this instrument.

The point of the perforator is commonly made much longer than is necessary. It ought not to pass more than the fifth or sixth part of an inch from the extremity of the canula; of this length it answers equally well as when the point is longer, and it is not so apt to wound the testis on being introduced into the cavity of the tunica vaginalis.

Fig. 24. Represents figs. 25. and 27. united, which is then called the *double gorgeret*, with the cutting blade *g, h*, affixed to it. This instrument is used in lithotomy, and recommended by Mr. Bromfield; (*vide supra*, n° 478, et seq.).

a, b, The handle of the hinder part.

c, d, The

Practice.

Practice.

c d, The grooved edge of the under gorgeret, that has received the edge of the upper gorgeret.

e, The beak of the under gorgeret.

f, The handle of the upper gorgeret, by which the instruments when united, are to be introduced into the bladder.

Fig. 25. The upper part of the double gorgeret, with the blade affixed for cutting the prostate gland; *g*, the cutting blade, which is blunt at *b*.

k, A hole or slit, through which the urine will pass as soon as the instrument enters the bladder. This observation will be a guide to the operator, as to the length of the incision he would wish to make of the prostate, by the farther introduction of the instrument when united.

1, The screw to fix the blade to the upper gorgeret.

Fig. 26. The posterior side of the double gorgeret when united for use.

e, The beak formed in the under gorgeret.

11, Shows the hollow of the two gorgerets when united, through which the urine comes out, when the extremity is got into the bladder.

Fig. 27. The under part of the double gorgeret separated from the upper, which varies but little in shape from the common gorgeret.

a, The beak; *bb*, the inner edges of the concave part, grooved as far as *cc* to permit the edges of the upper part to glide in, by which means they become one instrument at the time of introducing it.

Fig. 28. The upper part of the double gorgeret with its convex side uppermost; *f*, the handle; *ee*, the edges of the gorgeret made thin, so as to glide along the groove in the under part of the instrument.

d, The point, which, when united, forms the double gorgeret, and somewhat resembles the extreme part of a cow's horn. In this form it is a very great dilator, and a much safer instrument than the common gorgeret when the membranous part of the urethra only is wounded in the operation of lithotomy.

Fig. 29. The same instrument, only intended to show its internal or concave part.

Fig. 30. The cutting blade separated from the upper gorgeret.

1, A small hole through which a screw passes to fix it to the upper gorgeret, as is expressed by *l*, fig. 28.

m, A little hook-like part, which is received into a slit adapted to it in the upper gorgeret.

The space between *n, o*, is the only part of the blade that should cut.

N.B. Great care must be taken by the instrument-maker, to place the blade on the upper gorgeret in such direction, that its edge may incline obliquely downwards and outwards when the instrument is pushed on to divide part of the prostate gland.

Fig. 31. Mr Wathen's instruments for the cure of a fistula lachrymalis.

A, The ring at the top of the style.

B, The inferior extremity of the style rounded, so as to fill exactly the smaller end of the tube.

C, The shoulder; by means of which the style is prevented from passing further in the tube than it is designed it should.

D, The tube, with a small perforation near its upper or larger aperture for the admission of a thread.

E, The tube, with its thread in it.

F, G, H, The style, tube, and thread put together; which points out the manner in which the instrument is fitted for use.

1, The knot tied in the thread at the distance of an inch from the tube.

Fig. 32. Shows Mr Wathen's contrivance for keeping a broken limb steady. It is applicable either to the superior or inferior extremities; and in the figure is represented as applied to a compound fractured leg.

Fig. 33. Gives the skeleton of the machine which he calls a *conductor*, separated into two portions. The knee-band *a*, made of tin, a little bent; divided by four joints *b*, that it may fit any limb, great or small; holes *c*, for fixing the buckle and strap; others *d*, round each margin for sewing on the padding; two tin canulas *e*, grooved on the outside, and furnished on the inside with brass springs *f*, and catches *g*; small holes *h*, through which the catches pass to meet the serræ of the upright portions, when they are within the canulas.

The figure in the middle represents the inside of the tube with the groove.

Fig. 34. The ankle-band *a*, constructed as the knee-band, but less; shoulders *b*, to support and render the serrated portions parallel to the grooved canulas; both of brass.

By compressing the springs, the catches are raised, and admit the whole length of the upright serrated portions within the canulas; reducing the conductor to near half its length: from which reduction of the instrument, by the disposition of the catches and serræ, the canulas are retracted without difficulty, but cannot be returned the same way unless the catches are elevated by compressing the springs. By this means, when the conductor is fixed, the extension hereby given to the leg, whatever it be, is secured with the greatest certainty, tho' alterable with the utmost ease.

Fig. 35. The same instrument covered with leather, that it may fit easy on the limb.

Fig. 36. and 37. The improved splints applied upon a broken leg, so that the foot-pieces are plainly to be seen on both sides.

Fig. 38. Shows a machine invented by Mr Gooch for keeping up the hand, and allowing at the same time the motion of the fingers. This machine should be made a little concave, of light tough wood, such as beech, willow, or alder, and be covered with leather to be glued upon the wood. Its dimensions for a limb of a common size should be about ten inches long and three and a half broad. Besides the hooks shown upon the sides, it should have one in the middle. It is to be confined to the limb with filets tied upon stiff paper.

This very simple machine has been found of signal service in luxations of the wrist, and in fractures near that joint, as well as in other cases where it is necessary to have the hand supported, and also occasionally kept in gentle motion to preserve the flexure of the joint.

Rule-joints may be used to more advantage, where there is no occasion to drop the hand, and they will allow of a little motion upwards; when they are used, no hooks are required upon the machine.

(Surinam
||
Surveyor.

SURINAM, the capital of the Dutch settlements in Guiana, situated on a river of the same name, in N. Lat. 6. 16. W. Long. 56. o. It gives name to the country for 100 miles round; and stands on a river of the same name, which is navigable for 30 leagues up the country. Besides Surinam, there are seven or eight large towns, all rich and populous, and about 500 plantations. The colony is very flourishing, and carries on a considerable trade in sugar, tobacco, cotton, flax, dyeing woods, &c.

SURMOUNTED, in heraldry, is when one figure is laid over another.

SURNAME, or **SIRNAME**, a name added to the proper or baptismal name, to denote the person of such a family.

SURREPTITIOUS. See **SURREPTITIOUS**.

SURROGATE, in law, denotes a person that is substituted or appointed in the room of another.

SURRY, a county of England, bounded on the west by Berkshire and Hampshire, on the south by Sussex, on the east by Kent, on the north by Middlesex, from which it is parted by the Thames, whence it had the name of *Sub-rey* from the Saxons, i. e. the country on the south-side of the river. It is 34 miles in length from east to west, 21 in breadth from north to south, and 112 in circumference. It contains 13 hundreds, 140 parishes, of which 35 are vicarages, 11 market-towns, 450 villages, 592,000 acres, and about 170,000 inhabitants. The members sent from it to parliament are 14, of which two are sent by each of the following boroughs, viz. Southwark, Blechingley, Ryegate, Guildford, Gatton, Haslemere, and two for the county.

The air of this county, towards the middle consisting mostly of hills and heath, is sharp, but pure and wholesome. About the skirts, where it is more level, and the soil richer, the air is milder, but still salubrious. In the middle parts the soil is barren enough in general; but towards the extremities, and where the country is open and champaign, it is fruitful in grass and corn, particularly on the south side in Holmstead, in which meadows, woods, and corn-fields, are agreeably intermixed. The soil is also very fertile along the Thames, especially towards London, where it greatly contributes to maintain plenty in the London markets. It has several rivers, abounding with fish, the chief of which are the Wye, the Mole, and the Wandle. The first of these is of great benefit to the county, being navigable from Weybridge to the Thames, and thereby supplying many parts of it with necessities of all sorts. The Mole is so called because it runs about two miles under-ground, entering at a place named the *Swallower*, at the bottom of Boxhill, and emerging again, as is commonly thought, at Leatherhead. The chief articles of commerce produced in the county, are corn, boxwood, walnuts, and fullers-earth, which is sold at a great a bushel.

SURVEYING, the art of measuring land; that is, of taking the dimensions of any tract of ground, laying down the same in a map or draught, and finding the content or area thereof. See **GEOMETRY**.

SURVEYOR, a person who has the oversight and care of considerable works, lands, or the like.

SURVEYOR, likewise denotes a gauger; as also a person who surveys lands, and makes maps of them.

SURVIVOR, in law, signifies the longest liver of joint tenants, or of any two persons jointly interested in a thing.

SUS, in zoology, a genus of quadrupeds belonging to the order of belluae. They have four converging fore-teeth in the upper jaw, and six prominent ones in the under jaw; the snout is truncated, prominent, and moveable. There are five species. 1. The scropha, or common hog, with the body covered with bristles; two large teeth above and below. In a wild state, of a dark brindled colour, and beneath the bristles is a soft short hair; the ears short, and a little rounded. TAME: the ears long, sharp-pointed, and slouching; the colour generally white, sometimes mixed with other colours. In a tame state it is universal; except in the frigid zones, and in Kamtschatka, where the cold is very severe. Since its introduction into America by the Europeans, it abounds to excess in the hot and temperate parts. It is found wild in most parts of Europe. In the forests of South America there are vast droves, which derive their origin from the European kind relapsed into a state of nature; and are what Mr Bancroft in his History of Guiana, 126, describes as a particular species by the name of *Warree*. They cannot bear excessive cold; inhabit wooded countries; and are very swift. In America they are useful by clearing the country of rattle-snakes, which they devour with safety.

Of all quadrupeds, the hog is the most rude and brutal. The imperfections of his form seem to have an influence on his nature and dispositions. All his habits are gross; all his appetites are impure; all his sensations are confined to a furious lust, and a brutal gluttony. He devours indiscriminately every thing that comes in his way, even his own progeny the moment after their birth. This voraciousness seems to proceed from the perpetual cravings of his stomach, which is of an immoderate size; and the grossness of his appetites, it is probable, arises from the bluntness of his senses of taste and of feeling. The rudeness of the hair, the hardness of the skin, and the thickness of the fat, render these animals less sensible to blows. Mice have been known to lodge upon a hog's back, and to eat his skin and fat, without his showing any marks of sensibility. The other senses of the hog are very good. It is well known to the hunters that the wild boar hears and smells at a great distance; for, in order to surprize him, they are obliged to watch him in silence during the night, and to place themselves opposite to the wind, that he may not perceive the smell, which never fails to make him turn back.

But the hog, though the most impure and filthy of all quadrupeds, is yet useful by the very forbiddens of its manners; this alone devouring what is the refuse of all others, and contributing not only to remove what would be a nuisance to the human race, but also converting the most nauseous offals into the richest nutriment: for this reason its stomach is capacious, and its gluttony excessive: not that its palate is insensible to the difference of eatables; for where it finds variety, it will reject the worst with as distinguishing a taste as other quadrupeds.

The parts of this animal are finely adapted to its way of life. As its method of feeding is by turning up the earth with its nose for roots of different kinds,

Survivo
Sus.

Sus.

so nature has given it a more prone form than other animals; a strong brawny neck; eyes small, and placed high in the head; a long snout, nose callous and tough, and a quick sense of smelling to trace out its food. Its intestines have a strong resemblance to those of the human species. The external form of its body is very unwieldy; yet, by the strength of its tendons, the wild boar (which is only a variety of the common kind) is enabled to fly from the hunters with amazing agility: the back-toe on the feet of this animal prevents its slipping while it descends declivities, and must be of singular use when pursued. Yet, notwithstanding its powers of motion, it is by nature stupid, inactive, and drowsy; much inclined to increase in fat, which is disposed in a different manner from that of other animals, and forms a regular coat over the whole body. It is restless at a change of weather, and in certain high winds is so agitated as to run violently, screaming horribly at the same time: it is fond of wallowing in the dirt, either to cool its furcated body, or to destroy the lice, ticks, and other insects with which it is infested. Its diseases generally arise from foul feeding and intemperance; measles, imposthumes, and serophulous complaints, are reckoned among them. These are best prevented by keeping the animals, as the ancients strongly recommended, very clean in their flies; allowing them air, exercise, and a sufficiency of water. Linnæus observes, that its flesh is wholesome food for athletic constitutions, or those that use much exercise; but bad for such as lead a sedentary life: it is, however, of most universal use; and furnishes numberless materials for epicurism.

The boar, or male of these creatures, is chosen with great care, when intended for the propagation of his species; and is thus employed from the age of two to five years, and then either sold or fattened. The males not allotted to this use are castrated, sometimes at the age of six weeks, and sometimes when they are six months old; and then fed to a size either for sale or for the use of the family. Sows are kept for breed generally from one year old to seven, and are then spayed and fattened. They have commonly more grease on their intestines than hogs, these being fattest on their backs.

As to the age of these animals, it is said that the life of the wild boar may be extended to twenty-five or thirty years. Aristotle says, that hogs in general live twenty years; and adds, that both males and females are fertile till they arrive at the age of fifteen. They can engender at the age of nine or twelve months; but it is better to refrain till they be eighteen months or two years. The first litter of the sow is not numerous; and, when only one year old, her pigs are weak, and even imperfect. She may be said to be in season at all times. Though full, she solicits the approach of the male. This may be regarded as an excess among animals; for almost every other species refuse the male after conception. The ardour of the sow, though almost perpetual, is however marked by paroxysms and immoderate movements, which always terminate by her wallowing in the mire. She, at the same time, emits a thick whitish fluid. She goes four months with young; brings forth in the beginning of the fifth; and soon afterwards solicits the male, is impregnated a second time, and of course

brings forth twice a year. The wild sow, which every way resembles the domestic kind, produces only once a year. This difference in fertility is probably owing to want of nourishment, and the necessity of suckling her pigs much longer than the domestic sow, which is never allowed to nurse her young above fifteen days or three weeks. Only eight or nine of the litter are kept longer; the rest are sold. In fifteen days, pigs are excellent food.

As these creatures, though exceedingly voracious, will feed almost on any thing, they are bred and kept every where, and are quickly and cheaply fattened. In mire and in marshy grounds (from which they are not averse) they devour worms, frogs, fern, rush, and fedge roots. In drier and in woody countries, they feed on hips, haws, does, crabs, mast, chefnuts, acorns, &c. and on this food they will grow fleshy and fat. They are a kind of natural scavengers, will thrive on the trash of an orchard, the outcasts of the kitchen, the sweepings of barns and granaries, the offals of a market, and most richly on the refuse of a dairy. If near the sea, they will search the shores for shell-fish; in the fields, they eat grass; and in cities and large towns they are kept in great numbers, and supported chiefly by grains. It is evident that the facility of feeding them everywhere at a small expence, is a national benefit, more especially in a country where the people are accustomed to eat flesh daily, and could not perhaps perform their daily labour if they did not. It is no less observable, that notwithstanding this facility of feeding, and the multitudes of swine maintained, they seldom fail of coming to a good market. In no part of Europe is the management of these creatures better understood than in Britain. The time of farrowing is adjusted to the nature of the farm, the food it can supply; and the number of pigs sold and kept are in like manner adjusted. New kinds of food, more wholesome and nutritive than what were used formerly, have been introduced, such as turnips, carrots, clover, &c. They are in most places regularly managed and closely attended. Tuller, many years since, affirmed from his own experience, that a sow might bring as much profit as a cow. In some countries, it is said, a sow dependent on a dairy bath produced, all expences deducted, about 10*l.* in the space of a year. It may be some satisfaction to the reader to know, that, on a nice calculation, the annual profits of a sow in France are found to be between 50 and 60 livres.—In Britain, these animals in different counties are of very different sizes. In Leicestershire, Northamptonshire, and Pembrokehire, they are very large. In Hampshire, Wiltshire, and wherever they can run in the woods, and feed on mast and acorns, their flesh is firmer and better. The Chinese breed are common with us: they are smaller, blacker, and their legs shorter than ours; so that, when fat, their bellies literally touch the ground. They thrive exceedingly well with us, are very prolific, and their flesh admirably fine and well-tasted.

In considering the advantages derived from these creatures, it is to be observed, that the flesh of all their different kinds, and at all ages, is looked upon as a very substantial and agreeable aliment, and of course, in their proper seasons, the different sorts of provisions this supplies are all of them very saleable. The wild
boar

Sus.

boar was esteemed a prime delicacy amongst the Romans, and the flesh of the tame was much more in favour with our ancestors than with us; though BRAWN has still many admirers, is made in the greatest perfection, and considered as a rarity peculiar to this country. Pork, though it might be wisely prohibited in some warm countries, is found by experience equally nutritive and salutary here. As such it furnishes a very large proportion of that food which is vended in our markets. It takes salt better, and keeps longer, than the flesh of any other animal; and the consumption of it is prodigious when pickled or salted, more especially in our foreign garrisons and in the sea service. Our bacon is differently cured, so as to render it acceptable to all palates; and our hams are not at all inferior to those of other countries. Fresh pork sells nearly as dear as beef; the lard brings double or triple the price; the blood, the intestines, the feet, and the tongue, are all prepared as food. The fat of the intestines and web, which differs from common lard, is employed for greasing axles of wheels, and many other purposes. Sieves are made of the skin; and brushes, pencils, &c. of the bristles. The dung is reputed next in value to that of sheep. Mr Worlidge (Survey of Husbandry, p. 172.) proposes that swine should be turned into a clove, well-paled, and planted with greens, pulse, and roots, on which they may feed, and by their trampling and their dung raise a great quantity of excellent soil. Mr Mortimer assures us (Art of Husbandry, vol. i. p. 117.) that some, on poor light shallow land in Staffordshire, sow a small white pea, which they never reap, but turn in so many hogs to eat them as they think they will fat; and there they lie day and night, and their dung will so enrich the land, that it will bring a good sword upon it, and will graze many years afterwards. Our old husbandmen had an ill opinion of this dung, as supposing it bred weeds, which any dung will do that abounds in salts. In some places they wash with hogs dung for want of soap; which answers tolerably well, if the linen hangs long enough in the air to become thoroughly sweet.

The wild boar was formerly a native of our country, as appears from the laws of Hoeldda, who permitted his grand huntsman to chase that animal from the middle of November to the beginning of December. William the Conqueror punished with the loss of their eyes any that were convicted of killing the wild boar, the stag, or the roebuck; and Fitz-Stephen tells us, that the vast forest that in his time grew on the north-side of London, was the retreat of stags, fallow-deer, wild boars, and bulls. Charles I. turned out wild boars in the New Forest, Hampshire; but they were destroyed in the civil wars.

On the continent the wild boar is hunted with dogs, or killed by surprise during the night, when the moon shines. As he flies slowly, leaves a strong odour behind him, and defends himself against the dogs, and often wounds them dangerously, fine hunting dogs are unnecessary, and would have their nose spoiled, and acquire a habit of moving slowly by hunting him. Mastiffs, with very little training, are sufficient. The oldest, which are known by the tract of their feet, should only be attacked: A young boar of three years old is difficult to hunt down; because he runs very far far without stopping. But the older boars do not

run far, allow the dogs to run near, and often stop to repel them. During the day, he commonly remains in his soil, which is in the most sequestered part of the woods. He comes out in the night in quest of food. In summer, when the grain is ripe, it is easy to surprize him among the cultivated fields, which he frequents every night. As soon as he is slain, the hunters cut off his testicles, the odour of which is so strong, that in a few hours it would infect the whole flesh. The snout of an old boar is the only part that is esteemed; but every part of the castrated and young boar, not exceeding one year fed, makes delicate eating. The pork of the domestic boar is still worse than that of the wild boar; and it can only be rendered fit for eating by castration and fattening. The ancients castrated the young boars which they could carry off from their mothers, and returned them to the woods, where they grew fat, and their pork was much better than that of domestic hogs.

2. The athiopius, or Ethiopian hog, with small tusks in the lower jaw, very large ones in the upper, in old boars bending towards the forehead in form of a semicircle: no foreteeth: nose broad, depressed, and almost of a horny hardness; head very large and broad: beneath each eye a hollow, formed of loose skin, very soft, and wrinkled; under these a great lobe or wattle, lying almost horizontal, broad, flat, and rounded at the end, placed so as to intercept the view of any thing below from the animal. Between these and the mouth on each side, there is a hard callous protuberance. The mouth is small: skin dusky: bristles disposed in fasciculi, of about five each; longest between the ears and on the beginning of the back, thinly dispersed on the rest of the back. Ears large and sharp-pointed, inside lined with long whitish hairs: tail slender and flat, not reaching lower than the thighs, and is covered with hairs disposed in fasciculi. Body longer, and legs shorter, than in the common common swine: its whole length 4 feet 9 inches; height before, 2 feet 2 inches: but in a wild state, it grows to an enormous size.—These animals inhabit the hottest parts of Africa, from Senegal to Congo, also the island of Madagascar. We know little of their nature; but they are represented as very fierce and swift, and that they will not breed with the domestic sow.

3. The tajacu, or pecary, with four cutting teeth above, and six below: two tusks in each jaw; those in the upper jaw pointing down, and little apparent when the mouth is shut; the others hid: length from nose to the end of the rump about three feet: head not so taper as in common swine: ears short and erect: body covered with bristles, stronger than those of the European kind, and more like those of a hedge-hog; they are dusky, surrounded with rings of white; those on the top of the neck and back are near five inches long, grow shorter on the sides; the belly almost naked; from the shoulders to the breast is a band of white: no tail: on the lower part of the back is a gland, open at the top, discharging a fetid ichorous liquor; this has been mistakenly called a *navel*.—Inhabits the hottest parts of South America, and some of the Antilles: lives in the forests on the mountains: not fond of mire or marshy places: less fat than the common hog. They go in great droves. They are very fierce, and will fight stoutly with the beasts of prey: the ja-

Sus.
Sufa.

guar, or American leopard, is their mortal enemy; often the body of that animal is found with several of these hogs slain in combat. Dogs will scarce attack this animal: if wounded, it will turn on the hunters. They feed on fruits and roots; also on toads and all manner of serpents, which they hold with the fore-feet and skin with great dexterity. The flesh is reckoned very good food; but all writers agree that the dorsal gland must be cut out as soon as the animal is killed, or the flesh will become so infested as not to be eatable. The Indian name of this species is *paquiras*, from whence seems to be derived that of *pecary*.

Plate
CCLXXVI
fig. 1.

4. The babyrussa, or Indian hog, with four cutting teeth in the upper, six in the lower jaw; ten grinders to each jaw; in the lower jaw two tusks pointing towards the eyes, and standing near eight inches out of their sockets; from two sockets on the outside of the upper jaw two other teeth, twelve inches long, bending like horns, their ends almost touching the forehead: ears small, erect, sharp-pointed: along the back are some weak bristles; on the rest of the body only a sort of wool, such as is on the lambs: the tail long, ends in a tuft, and is often twisted: the body plump and square. Inhabits Buero, a small isle near Amboina: it is also found in Celebes, but neither on the continent of Asia or Africa; what M. de Buffon takes for it is the Ethiopian boar. They are sometimes kept tame in the Indian isles: live in herds: have a very quick scent: feed on herbs and leaves of trees; never ravage gardens like other swine: their flesh well-tasted. When pursued and driven to extremities, they rush into the sea, swim very well, and even dive, and pass thus from isle to isle. In the forests they often roll their heads, by hooking their upper tusks on some bough. The tusks, from their form, are useless in fight.

5. The hydrocheris, or river-hog, has a very large and thick head and nose; small rounded ears; large black eyes; upper jaw longer than the lower: two strong and great cutting teeth, and eight grinders, in each jaw; and each of those grinders form on their surface seemingly three teeth, each flat at their ends: legs short; toes long, connected near their bottoms by a small web; their ends guarded by a small hoof: no tail: hair on the body short, rough, and brown; on the nose, long and hard whiskers. It grows to the size of a hog of two years old.—Inhabits the eastern side of South America, from the isthmus of Darien to the river of Amazons: lives in the fenny parts not remote from the banks of great rivers: runs slowly; swims and dives remarkably well, and keeps for a long time under water: feeds on fruits and vegetables: is very dexterous in catching fish, which it brings on shore and eats at its ease: it sits up, and holds its prey with its fore-feet, feeding like an ape: feeds in the night, and commits great ravages in gardens. They keep in large herds, and make a horrible noise like the braying of an ass. The flesh is tender, but has an oily and fishy taste. They are easily made tame, and grow very fat.

SUSA, the ancient royal residence of the kings of Persia, built by Darius Hytaspis, according to Piny; though he probably only restored it, being a very ancient city, founded by Tithonus father of Memnon. It was in compals 120 stadia, of an oblong quadran-

gular form, with a citadel called *Memnoneum*. In scripture it is called *Susan*, the royal citadel, from the great number of lilies growing in that district (Athenaeus); situate on the river Uhlai, or Euleus (Daniel): and the Spaniards call at this day a lily *ajafena* (Pinedo.) Sufa was the winter, as Ecabatana was the summer, residence of the kings of Persia, (Xenophon, Strabo, Plutarch.) Here the kings kept their treasure, (Herodotus.) Now called *Tufter*.

SUSPENSION, in Scots law. See LAW, N° clxxxv. 5. 6. 7.

SUSSEX, a county of England, deriving its name from its situation in respect of the other Saxons, and called *Suffex*, i. e. the country of the South Saxons, has Hampshire on the west, the British channel on the south, Surrey on the north, and Kent on the east. Its length is 65 miles, its breadth 29, and its circumference 170. It is divided into 6 rapes, and these into 65 hundreds, in which are 312 parishes, of which 123 are vicarages, one city, 18 market-towns, 1060 villages and hamlets, and about 120,000 thousand souls. It has few good ports, though it lies along the channel for 65 miles, which is its greatest length, the coast being encumbered in many places with rocks; and where it is more open, such quantities of sand are thrown upon it by the south-west winds, and the harbours so choked up, that they will not admit vessels of any great draught or burden. The county is well watered by the rivers Arun, Adar, Ouse, Rother, Lavant, Cuckmeer, Ashburn, and Aften, by which it is well supplied with fish, as well as from the sea. Hence different places of the county are famed for different sorts of fish, as the Arun for mullets, which enter it from the sea in summer in shoals, and by feeding upon a particular kind of herb become extremely delicious; Chichester for lobsters, Selsey for cockles, Amberley for trout, Pulborough for eels, Rye for herrings, and the county in general for carp. It is remarkable, that all the rivers above-mentioned rise and fall into the sea within the county.

The air, as well as the soil, is various in different parts of the county. Upon the coast the air is aguish, upon the hills and downs pleasant and wholesome; but somewhat moist and foggy in the valleys, the soil being deep and rich, and the vegetation in summer very vigorous. The downs in some places are very fertile in corn and grass; in others they feed great flocks of sheep, whose flesh and wool are very fine; but of the latter no inconsiderable quantity is clandestinely exported to France. In the Weald and the valleys the roads are very deep, especially in winter. In the north quarter are many woods, and some forests in other places; whence the king's yards are supplied with the largest and best timber in England, beside what is made into charcoal and consumed in the iron-works; for on the east side is plenty of iron ore, with furnaces, forges, and mills for manufacturing it. The gunpowder of this county is said to excel that of any other. Those delicious birds called *wheat-eats* are bred in this shire: they are no bigger than a lark, but almost an entire lump of fat. That part now called the *Wild or Weald* of Sussex, was anciently a mere desert for hogs and deer, of great extent, taking in a part of Kent and Surrey; and was called *Andridera Silva*, *Coid Andred*, and *Andradwald*, from *Andridera*

Suspension
Sussex.

Sutherland. an adjoining city. This county is in the home-circuit and diocese of Chichester, giving title of earl to the family of Yelverton, and sends 28 members to parliament, viz. two for the county, two for the city of Chichester, and two for each of the following towns, Horsham, Lewis, Bramber, East-Grinstead, Midhurst, Shoreham, Steyning, Arundel, Hailings, Rye, Winchelsea, and Seaford; of which the four last are cinque-ports.

SUTHERLAND, one of the most northerly counties of Scotland. Including Strathnavern, it borders on Caithness to the east and north-east, is bounded by the ocean on the north, the country of Aylshy on the west, Ross on the south, and by the German sea on the east and south-east. It stretches about 80 miles in length, and 40 in breadth; is generally hilly, though in many parts arable; well watered with small rivers and streams replete with fish, and exhibiting about 60 lakes, the habitation of various fish, swans, ducks, geese, &c. The largest of these is Lochfyn, extending 41 miles in length: some of them are interperfed with small verdant islands, which in summer yield a very agreeable prospect. On the coast are many commodious harbours, and all the bays swarm with fish; nay, the sea in this place produces some valuable pearls. Sutherland affords iron, stone, free-stone, lime-stone, and slate, in abundance. Here are also quarries of marble, and mines of coal, though the people use turf and peat for fuel. Lead-ore, impregnated with silver, and even some gold, hath been found in this province, together with crystals and pebbles.

The air is so temperate, and the soil so good, that saffron has here been brought to perfection. Many parts of the country are remarkably fruitful in corn, and the pasturage is excellent every where. Besides three great forests, there are many smaller woods in Sutherland, abounding with deer and other game. On the hills are fed numerous flocks of sheep and black cattle; small, yet sweet and juicy. There is one bird peculiar to this shire, called *knag*, which resembles a parrot, and digs its nest with its beak in the trunks of oaks. The northern part, called *Strathnavern*, and separated from the rest by a ridge of mountains, is bounded on the north and west by the Deucaledonian and Vergivian oceans, on the east by Caithness, and on the south by Aylshy. The length of it, from east to west, amounts to 34 miles; but the breadth from north to south does not exceed 12 in some places. It is very hilly; and the mountains are so high, that the snow remains on the tops of them till midsummer. It is watered by Naver, from whence it derives its name: as this district gives a title to the eldest son of the earl of Sutherland. Here are several woods, frequented by deer and other game, which the people take great delight in hunting. Iron-mines have been worked in some places, but to no great advantage. Strathnavern has many fresh-water lakes or lochs; the chief of which are Loch Naver, and Loch Lye: there are several islands on the northern coast; and in various parts of the country we see monuments of victories obtained over the Danes or other foreign invaders. Sutherland boasts of some towns, and a great many villages. The people are numerous, hardy, bold, and enterprising; courteous to strangers; cheer-

ful, open, frugal, and industrious. They, as well as their neighbours of Caithness, speak the language, and wear the garb, used in the Lowlands of Scotland. They carry on a considerable salmon-fishery. They drive a traffic with their black cattle, sheep, and horses, at the neighbouring fairs; but export their corn, barley, salt, coal, salmon, salted beef, butter, cheese, wool-skins, hides, and tallow. Here are provisions of all sorts in plenty; and so cheap through all this country, that a gentleman may keep house and live much more sumptuously for 200*l.* a year than he can live for three times the money in the south of England.

SUTLER, in war, on who follows the army and furnishes the troops with provision. They pitch their tents, or build their huts, in the rear of each regiment, and about head-quarters.

SUTRIUM, (anc. geog.) a famous city, and an ancient colony of the Romans; the key of Etruria. The colony led seven years after the taking of Rome by the Gauls, (Velleins). Now *Sutri* in St Peter's patrimony, on the river Pozzolo; surrounded on every side with rocks, 24 miles to the north-west of Rome.

SUTTON (Samuel), was born at Alfreton in Derbyshire, and going into the army served under the duke of Marlborough in queen Anne's wars with great credit. He afterwards came to London, commenced brewer, and kept a coffee-house in Aldersgate street, which was well frequented by the learned men of that time, by whom Mr Sutton was much respected, as a man of strong natural parts and uncultivated genius. About the year 1740, he schemed a very simple and natural method for extracting the foul air from the wells of ships, by pipes communicating with the fire places of the coppers; which operated as long as any fire was kept burning for the ship's use. In this happy invention, so conducive to the safety of mariners, he met, however, with a formidable competitor in Dr Stephen Hales; who was at the same time engaged in promoting his own ventilators: tho' these ventilators were by no means so well adapted to sea-use, where room and labour are precious, as Sutton's air pipes; which could scarcely be said to occupy any room, and required no labour to work them, as they produced a regular circulation of air, on philosophical principles. Nevertheless, though Mr Sutton's invention was warmly patronized by Dr Mead and Dr Watson, it was ungenerously discouraged by some leading men in the navy department. Dr Mead annexed an account of these air-pipes, and the history of the author's difficulties in procuring a fair trial to be made of them, to his Discourse on the Scurvy. Mr Sutton took out a patent in 1744, to secure the profits of his invention to himself; and died about the year 1752.

SUTTON'S Air-pipes. See *Air-Pipes*.

SWABBER, an inferior officer on board ships of war, whose employment it is to see that the decks are kept clean and neat.

Swallow
||
Swammerdam.

SWALLOW, in ornithology. See *Hirundo*.

SWALLOW-*Wort*, in botany. See *Asclepias*.

SWAMMERDAM (John), a celebrated and learned natural philosopher, was the son of John James Swammerdam, an apothecary and famous naturalist of Amsterdam, and was born in 1637. His father intended him for the church, and with this view had him instructed in Latin and Greek; but he, thinking himself unequal to so important a task, prevailed with his father to consent to his applying himself to physic. As he was kept at home till he should be properly qualified to engage in that study, he was frequently employed in cleaning his father's curiosities, and putting every thing in its proper place. This inspired our author with an early taste for natural history; so that, not content with the survey of the curiosities his father had purchased, he soon began to make a collection of his own, which he compared with the accounts given of them by the best writers. When grown up, he seriously attended to his anatomical and medical studies; yet spent part of the day and the night in discovering, catching, and examining the flying insects proper to those different times, not only in the province of Holland, but in those of Guelderland and Utrecht. Thus initiated in natural history, he went to the university of Leyden in 1651; and, in 1663, was admitted a candidate of physic in that university. His attention being now engaged by anatomy, he began to consider how the parts of the body, prepared by dissection, could be preserved, and kept in constant order for anatomical demonstration; and herein he succeeded, as he had done before in his nice contrivances to dissect and manage the minutest insects. Our author afterwards made a journey into France, where he spent some time at Saumur, and where he became acquainted with several learned men. In 1667, he returned to Leyden, and took up his degree of doctor of physic. The next year the grand duke of Tuscany being in Holland, in order to see the curiosities of the country, came to view those of our author and his father; and on this occasion Swammerdam made some anatomical dissections of insects in the presence of that prince, who was struck with admiration at our author's great skill in managing them, especially at his proving that the future butterfly lay with all its parts neatly folded up in a caterpillar, by actually removing the integuments that covered the former, and extricating and exhibiting all its parts, however minute, with incredible ingenuity, by means of instruments of inconceivable fineness. On this occasion the duke offered our author 12,000 florins for his share of the collection, on condition of his removing them himself into Tuscany, and coming to live at the court of Florence; but Swammerdam, who hated a court life, declined his highness's proposal. In 1663, he published a *General History of Insects*. About this time, his father began to take offence at his inconsiderately neglecting the practice of physic, which might have supported him in affluence; and would neither supply him with money nor cloaths. This reduced him to some difficulties. In 1675, he published his *History of the Ephemeræ*; and his father dying the same year, left him a fortune sufficient for his support: but he did not long survive him, for he died in 1682. Gausubius gave a translation of all

his works from the original Dutch into Latin, from which they were translated into English, in folio, in 1758. The celebrated Boerhaave wrote his life.

SWAN, in ornithology. See *Anas*.

SWANPAN, or Chinese *ANACUS*; a board or instrument for performing arithmetical operations, described by Du Halde in his *History of China*. The following construction is an improvement of that by Mr G. Smethurst, published in the *Gent. Mag.* for 1748.

In the square frame of wood *ABCD*, are four Plate divisions formed by the bars *EF* and *GH*; of these *CCLXX*. divisions three are separated into two parts by the lesser bars *ab*. In each of the smaller divisions are placed wires, to be taken out at pleasure; and on each of the wires in the left-hand divisions is strung a small ivory ball, or large bead; and on the wires on the right-hand division are placed four such balls or beads.

The balls in the left-hand divisions, when brought up to the middle bar, stand each for five; and those in the right divisions, when brought to the bar, stand for units.

The balls in the two lower divisions represent integers, or the whole of any quantity; those on the uppermost wires stand for ten of such integers, the next for hundreds, and so on, as is expressed in the figure. The wires, in all the divisions, may be increased to any number you think proper.

The balls in the four upper divisions represent parts of integers; those in the two divisions next the left-hand stand for tens; and those in the two other divisions, for units of such parts.

Now if the sum you would set down be integers, begin with the balls in the two lower divisions: for example, on the third row from the top bring two balls, of the right-hand division, up to the middle bar (see the figure); then bring up two on the next row, and one on the same row in the left division; next, four on the top row, and one on the other side of the same row: then in the first row of units, from the bottom, and in the right-hand division, place two balls, on the second row one, and one also on the same line in the right-hand division of tens; lastly, on the third row of units place three balls. The balls being thus placed, if the integers be pounds sterling, they will express 279 l. 2s. 11 d. If the integers be hundred weights, the sum will be 279 cwt. 2 qrs. 11 lb. 3 oz.; or if they be years, they will denote 279 years, 2 months, 11 days, 3 hours.

A part of these balls may represent fractions, either vulgar or decimal: the balls in the first two divisions of parts may stand for the numerators, and those in the other two for denominators; or the numbers in either of these divisions may be added to those in the integers, as decimals. There may also be holes made in the bars where the dots are placed, in which pegs may be occasionally put, to show that those numbers stand for fractions.

By this instrument all the operations of arithmetic may be readily performed. Suppose, for example, you would multiply the sum set down in the division of integers, that is, 279, by 3. Begin with the lowest line, and say 3 times 2 is 6, therefore set that number up; then on the next row, say 3 times 7 is 21, therefore instead of 7 set up 1 on that line, and carry the

Swan,
Swanpan.

Swanpan
|
Sweden.

the two tens to the line below, which will make the number there 8. Then at the upper line say, 3 times 9 is 27, therefore set 7 on that line, and carry 2 to the next line below, which will make that number 3. So that the balls on the three lines will then express 837.

If you would divide 279 by 3, begin in like manner with the lowest line: but as 3 cannot be taken in 2, you add the next number to it, and say, the threes in 27 are 9; therefore set back the 2 on the lowest line, and place 9, instead of 7, on the next line above: then at the uppermost line say, the threes in 9 are 3; therefore instead of 9 place 3 on that line, and consequently the quotient will be 93. When there is a remainder, it may be placed with the divisor, as a fraction, in the upper divisions. Where there are many figures in the multiplicand and multiplier, the latter may be placed in the first two divisions of parts, and the former and products in the divisions of integers. In like manner, when there are several figures in the dividend and divisor, the former may be placed in the division of integers, the latter in the first two divisions of parts, and the figures of the quotient, as they rise, in the remaining two divisions.

It is well worth observing, that by means of this instrument a blind man may be taught to add, subtract, multiply, divide, and perform all the other operations of arithmetic, with as much certainty as another person can by figures.

SWANEMOTE, SWAINMOTE, or SWEINMOTE. See FOREST-COURT.

SWEAT, a sensible moisture issuing from the pores of the skins of living animals.

SWEDEN, one of the most northerly kingdoms of Europe, lying between Lat. 55. 20. and 69. 30. north, and between 12° and 32° east from London. On the south it is bounded by the Baltic, the Sounds, and Schager-rack, or Categate; on the north by Danish Lapland; on the east by Muscovy; and on the west by the mountains of Norway.

The early history of Sweden is no less involved in fables than that of most other nations. Some historians have pretended to give regular catalogues of the princes who reigned in Sweden in very early times; but they differ so much among themselves, that no credit can be given to them. However, all agree that ancient Scandinavia was first governed by judges elected for a certain time by the voice of the people. Among these temporary princes the country was divided, until, in the year of the world 2054, according to some, or 1951, according to others, Eric, or, if we believe Puffendorf, *Suenon*, was raised to the supreme power, with the prerogatives of all the temporary magistrates united in his person for life, or until his conduct should merit deposition.

From this very early period till the year 1366 of the Christian era, the histories of Sweden present us with nothing but what is common to all nations in their early periods, viz. the endless combats and massacres of barbarians, tending to no other purpose than the effusion of blood. At the time just mentioned, however, Albert of Mecklenburg, having concluded a peace between Sweden and Denmark, which two kingdoms had been at violent war for some time before, was proclaimed king of Sweden. The peace

was of short duration, being broken in 1368; on which Albert entered into an offensive and defensive league with the earl of Holstein, the Jutland nobility, the dukes of Sleswick, Mecklenburg, and the Hanse-towns, against the kings of Denmark and Norway. Albert proved very successful against Waldemar king of Denmark at that time, driving him entirely out of his dominions; but he himself was defeated by the king of Norway, who laid siege to his capital. Soon after this, a new treaty of peace was concluded, by which Albert was allowed to enjoy the crown of Sweden in peace. However, having formed a design of rendering himself absolute, he fell under the displeasure of his subjects, and Margaret of Norway was proclaimed queen of Sweden by the malcontents. A war immediately ensued, in which Albert was defeated and taken prisoner; but as the princes of Mecklenburg, the earls of Holstein, and the Hanse-towns entered into a league in his favour, the war was so far from being extinguished by this event, that it raged with more fury than ever.

At length, in 1394, the contending parties came to an accommodation. Albert was set at liberty, on condition that he should in three years surrender to Margaret all pretensions to the city of Stockholm; and the Hanse-towns engaged to pay the sum of 60,000 marks of silver in case of Albert's breach of faith. Not long after this, Eric the son of Albert died; and he, having no other child, did not think it worth his while to contend for the kingdom of Sweden: he therefore acquiesced in the pretensions of Margaret, and passed the remainder of his days at Mecklenburg.

Margaret died in 1415, and was succeeded by Eric of Pomerania. This prince's reign was cruel and oppressive to the last degree. The people were ruined by taxes; and the Danes being every where preferred to the offices of power, committed the greatest cruelties. The consequence of this was a revolt; and Charles Canutson, grand marshal of Sweden and governor of Finland, having joined the malcontents, was declared commander in chief of their army. Eric was now formally deposed, and commenced pirate: Canutson was chosen regent; but beginning to oppress the people, and aspiring openly at the crown, the Swedes and Danes revolted; in consequence of which a revolution took place, and Christopher duke of Bavaria, nephew to Eric, was chosen king of Denmark, Sweden, and Norway, in 1442.

On the accession of the new prince, complaints against Canutson were brought from all quarters; but, through the interest of his friends, he escaped the punishment due to him; and in 1448, Christopher having died after a tyrannical reign of somewhat more than five years, he was raised to the throne at which he had so long aspired. However, the kingdoms of Denmark and Norway refused to own allegiance to him; upon which a war immediately commenced. In 1454 peace was concluded, and Denmark for the present freed from the Swedish yoke. Neither did Canutson long enjoy even the crown of Christian Sweden itself. Having quarrelled with the archbishop of Upsal, the latter formed such a strong party that the king could not resist him. Christian king of Denmark was called to the throne of Sweden; and in 1459 once more united the three kingdoms. He is driven out.

enjoyed his dignity but a short time; for having begun to oppress his subjects in an arbitrary manner, he was obliged to retire to Denmark in 1463. Katil bishop of Lincoping, who had driven out the king, took upon himself the office of regent. Next year Christian returned with a powerful army; but was defeated. The people then thought proper to recal Canutson: but he, on his first accession, having offended the warlike bishop Katil, was by him defeated, and obliged to renounce his right to the crown. After this the kingdom was rent into factions; between whom the most cruel civil wars took place, until the year 1467, when Canutson was again recalled, and enjoyed the kingdom, though not without difficulty and opposition, till his death, which happened in 1470.

The confusion in which the Swedish affairs had been so long involved did not cease on the death of Canutson. Christian again invaded Sweden; but was defeated by Steen Sture, nephew to the late king. After this the kingdom seems to have remained in peace till the year 1487, when the Russians invaded Carelia, committing every where the greatest ravages. These were soon driven out: but in 1497, a rupture happening betwixt Sture and the senate, an offer was made of the Swedish crown to John king of Denmark. This prince readily accepted the offer, and was crowned accordingly; but no sooner was he seated on the throne than he became odious to the Swedes, from his partiality to the Danes. In a short time he set out for Denmark, leaving his queen, with a strong garrison, in the citadel of Stockholm. He was no sooner gone than the capital was invested; and though the queen made a noble defence, she was at last obliged to capitulate, on condition of being allowed to pass into Denmark. All the garrison were made prisoners of war, and the queen herself was confined in a monastery till the following year.

The Swedish affairs continued to be involved in the same dreadful confusion as we have already related, until the year 1520, when a great revolution was effected by Gustavus Ericson, a nobleman of the first rank, who restored the kingdom to its liberty, and laid the foundation of its future grandeur. The occasion of this great revolution was as follows: In 1518, Christian king of Denmark invaded Sweden, with a design to subdue the whole country: but being defeated with great loss by young Steen Sture, the regent at that time, he set sail for Denmark. But meeting with contrary winds, he made several descents on the Swedish coast, which he ravaged with all the fury of an incensed barbarian. The inhabitants, however, bravely defended themselves, and Christian was reduced to the utmost distress; one half of his forces having perished with hunger, and the other being in the most imminent danger by the approach of a rigorous winter. He then thought of a stratagem, which had almost proved fatal to the regent; for having invited him to a conference, at which he designed either to assassinate or take him prisoner, Sture was about to comply, had not the senate, who suspected the plot, interposed and prevented him. Christian then offered to go in person to Stockholm in order to confer with Sture, upon condition that six hostages were sent in his room. This was accordingly done; but the wind

happening then to prove favourable, he set sail for Denmark with the hostages, of whom Gustavus Ericson was one. Next year he returned; and having drawn Sture into an ambush, the regent received a wound of which he died some time after. The kingdom being thus left without an head, matters soon came to the most desperate crisis. The army disbanded itself; and the senate, instead of taking proper measures to oppose the enemy, spent their time in idle debates. Christian in the mean time advanced into the heart of the kingdom, destroying every thing with fire and sword; but on his arrival at Stragnez, he granted a suspension of arms, to give the people time to deliberate on their situation, and to reflect that they might easily get rid of their troubles by electing him king. This they accordingly did; and Christian proved one of the most bloody tyrants that ever sat on the throne of any kingdom. Immediately after his coronation, he gave grand entertainments for three days; during which time he projected the diabolical design of extirpating at once all the Swedish nobility, and thus for ever preventing the people from revolting, by depriving them of proper leaders. As the tyrant had signed articles, by which he promised indemnity to all who had borne arms against him, it became necessary to invent some cause of offence against those whom he intended to destroy. To accomplish his purpose, Gustavus Trolle, formerly archbishop of Upsal, but who had been degraded from that dignity, in an oration before his majesty lamented the demolition of Steckas his place of residence, and the losses sustained by the see of Upsal, amounting to near a million of money. He then proceeded in a bitter accusation against the widow and the son-in-law of Sture the late regent, comprehending in the same accusation about 15 of the principal nobility, the whole senate, and the burghers of Stockholm. The consequence of this was, that above 60 of the principal nobility and people of first rank in Sweden were hanged up as traitors. Innumerable other cruelties were committed; part of which are owned by the Danish historians, and minutely related by those of Sweden. At last he departed for Denmark, ordering gibbets to be erected, and causing the peasants to be hanged on them for the slightest offences, all the way as he passed along; and it is related of him, that at Jencoping he caused two boys, one of seven and the other of nine years of age, to be whipped to death.

This monstrous cruelty, instead of securing him on the throne, exasperated the whole nation against him. It has already been mentioned, that Gustavus Ericson, or, as he is commonly called, *Gustavus Vasa*, was among the number of the hostages whom Christian had perfidiously carried to Denmark in 1519. Large promises had been made in order to reconcile him to Christian, and threats had been used for the same purpose, but all in vain. Secret orders were given to strangle him in prison; but the officer to whom the assassination was committed remonstrated to the king about the consequences of it, and prevailed on him to change the sentence of death into close confinement in the castle of Copenhagen. Some of the hostages perished in consequence of the rigorous treatment they met with; but Gustavus withstood all hardships. At last one Banner, a Danish nobleman, pre-
vailed

Sweden.

¹¹ He treacherously carries off six hostages of, whom Gustavus Ericson is one.

¹² Is chosen king, and proves a most bloody tyrant.

¹³ Massacres the nobility, and causes gibbets to be erected as usual along.

¹⁴ Adventures of Gustavus Vasa or Ericson.

vailed on the king to put him into his hands, in order to try whether or not he could prevail upon him to change his sentiments. The king, however, told Banner, that he must pay 6000 crowns in case the prisoner should make his escape. Banner generously assented; and having brought the noble prisoner to his fortrefs of Calo in Jutland, soon allowed him all the liberty he could desire, and otherwise heaped favours upon him. All this, however, could not extinguish his remembrance of the cruelties of Christian, and the desire he had of being serviceable to his country. He therefore determined to make his escape; and the liberty he enjoyed soon put him in a capacity of effecting it. Having one day mounted his horse, under pretence of hunting as usual in the forest, when he got at a proper distance, he changed his dress to the habit of a peasant; and quitting his horse, he travelled for two days on foot through by-paths, and over mountains almost impassable, arriving on the third at Flensburg. Here no one was admitted without a passport; and Gustavus dreaded presenting himself to the governor or the officer upon guard, for fear of being discovered. Happily for him, it chanced to be on that season of the year when the merchants of Lower Saxony drove a considerable trade in cattle, which they purchase in Jutland. Gustavus hired himself to one of these merchants; and under favour of his disguise escaped out of the Danish territories, and arrived at Lubeck.

Banner was no sooner acquainted with his escape, than he set out after him with the utmost diligence, found him at Lubeck, and reproached him with great warmth as ungrateful and treacherous; but he was soon appeased by the arguments urged by Gustavus, and especially by the promise he made of indemnifying him in the loss of his ransom. Upon this Banner returned, giving out that he could not find his prisoner. Christian was enraged at his escape, apprehending that he might traverse all his designs in Sweden; and gave orders to Otho his general to make the strictest search, and leave no means untried to arrest him. Gustavus applied to the regency for a ship to convey him to Sweden, where he hoped he should be able to form a party against the Danes. He likewise endeavoured to draw the regency of Lubeck into his measures; and reasoned with so much zeal and ability, that Nicholas Gemina, first consul, was entirely gained: but the regency could never be prevailed on to declare for a party without friends, arms, money, or credit. However, before his departure, the consul gave him assurances, that if he could raise a force sufficient to make head against the enemy in the field, he might depend on the services of the republic, and that the regency would immediately declare for him. Gustavus desired to be landed at Stockholm; but the captain of the ship, either having secret orders to the contrary, or business elsewhere, steered a different course, and put him on shore near Calmar, a city hitherto garrisoned by the troops of Christina widow of the regent. In truth, the governor held this place for his own purposes, and only waited to make the best terms he could with the Danes. When Gustavus arrived, he made himself known to him and the principal officers of the garrison, who were mostly Germans, and his fellow-soldiers in the late administra-

tor's army. He flattered himself that his birth, his merit, and connections, would immediately procure him the command. But the mercenary band, seeing him without troops and without attendants, regarded him as a desperate person devoted to destruction, refused to embrace his proposals, and even threatened to kill or betray him if he did not instantly quit the city.

Disappointed in his expectations, Gustavus departed with great expedition; and his arrival being now publicly known, he was again forced to have recourse to his peasant's disguise to conceal him from the Danish emissaries dispersed over the country to search for him. In a waggon loaded with hay he passed thro' every quarter of the Danish army, and at last repaired to an old family-castle in Sundermania. From hence he wrote to his friends, notifying his return to Sweden, and beseeching them to assemble all their force in order to break through the enemy's army into Stockholm, at that time besieged; but they, too, refused to embark in so hazardous and desperate an attempt.

Gustavus next applied himself to the peasants: but they answered, that they enjoyed salt and herring under the government of the king of Denmark; and that any attempts to bring about a revolution would be attended with certain ruin, without the prospect of bettering their condition; for peasants they were, and peasants they should remain, whoever was king. At length, after several vain attempts to throw himself into Stockholm, after that city was surrendered to the king, after the horrid massacre of the senate, and after running a thousand dangers, and undergoing hardships and fatigues hardly to be supported by human nature, he formed the resolution of trying the courage and affection of the Dalecarlians. While he was in the deepest obscurity, and plunged in almost insurmountable adversity, he never relinquished his designs or abandoned hope. The news of the massacre had, however, very near sunk him in depondency, as thereby he lost all his friends, relations, and connections, and indeed almost every prospect of safety to himself or deliverance to his country. It was this that inspired the thought of going to Dalecarlia, where he might live with more security in the high mountains and thick woods of that country, if he should fail in the attempt of exciting the inhabitants to revolt.

Attended by a peasant, to whom he was known, he travelled in disguise through Sundermania, Nericia, and Westermania, and arrived, after a laborious and painful journey, safe in the mountains of Dalecarlia. Scarce had he finished his journey, when he found himself deserted by his companion and guide, who carried off with him all the money he provided for his subsistence. Thus forlorn, destitute, half starved, he entered among the miners, and wrought like a slave under ground, without relinquishing his hopes of one day ascending the throne of Sweden. His whole prospect for the present was to live concealed, and gain a maintenance, until fortune should effect something in his favour: nor was it long before this happened. A woman in the mines perceived, under the habit of a peasant, that the collar of his shirt was embroidered. This circumstance excited curiosity; and the graces of his person and conversation, which had something in them to attract the notice of the meanest of the vul-

gar, afforded room for suspicion that he was some person of quality in disguise, forced by the tyranny of the government to seek shelter in these remote parts. The story came to the ears of a neighbouring gentleman, who immediately went to the mines to offer his protection to the unfortunate stranger; and was astonished on recognising the features of Gustavus, whose acquaintance he had been at the university of Upsal. Touched with compassion at the deplorable situation of so distinguished a nobleman, he could scarce refrain from tears; but however had presence of mind enough not to make the discovery. At night he sent for Gustavus, made him an offer of his house, and gave him the strongest assurances of his friendship and protection. He told him, he would meet with better accommodations, and as much security as in the mines; and that, should he chance to be discovered, he would, with all his friends and vassals, take arms in his defence.

This offer was embraced by Gustavus with joy, and he remained for some time at his friend's house; but finding it impossible to induce him to take part in his designs, he quitted him, and fled to one Peterson, a gentleman whom he had formerly known in the service. By him he was received with all the appearance of kindness; and, on the very first proposal made by Gustavus, offered to raise his vassals. He even named the lords and peasants whom he pretended to have engaged in his service; but in a very few days after, he went secretly to a Danish officer, and gave him information of what had passed. The officer immediately caused the house to be surrounded with soldiers, in such a manner that it seemed impossible for Gustavus to make his escape. In the interval, however, he was gone, being warned by Peterson's wife of the treachery of her husband, and by her direction fled to the house of a clergyman, her friend. By him Gustavus was received with all the respect due to his own birth and merit; and left the domestic who conducted him should follow the treacherous example of his master, he removed him to the church, and conducted him to a small closet, of which he kept the key. Having lived for some time in this manner, Gustavus began to consult with his friend concerning the most proper method of putting their schemes in execution. The priest advised him to apply directly to the peasants themselves; told him that it would be proper to spread a report, that the Danes were to enter Dalecarlia in order to establish new taxes by force of arms; and as the annual feast of all the neighbouring villages was in a few days to be held, he could not have a more favourable opportunity: at the same time he promised to engage the principal persons of the diocese in his interest.

Agreeable to this advice Gustavus set out for Mora, where the feast was to be held. He found the peasants already informed of his designs, and impatient to see him. Being already prepossessed in his favour, they were soon excited to an enthusiasm in his cause, and instantly resolved to throw off the Danish yoke. In this design they were more confirmed by their superstitious; some of their old men having observed that the wind had blown from the north while Gustavus was speaking, which among them was reckoned an infallible omen of success. Gustavus did not give their

ardour time to cool, but instantly led them against the governor's castle; which he took by assault, and put the garrison to the sword. This inconsiderable enterprise was attended with the most happy consequences. Great numbers of the peasants flocked to his standard; some of the gentry openly espoused his cause, and others supplied him with money. Christian was soon acquainted with what had passed; but despising such an inconsiderable enemy, he sent only a slender detachment under the command of one Soren Norby, to assist his adherents in Dalecarlia. Gustavus advanced with 5000 men, and defeated a body of defeated. Danes commanded by one Meleen; but he was strenuously opposed by the archbishop of Upsal, who raised numerous forces for king Christian. The fortune of Gustavus, however, still prevailed, and the archbishop was defeated with great loss. Gustavus then laid siege to Stockholm; but his force being too inconsiderable for such an undertaking, he was forced to abandon it with loss.

This check did not prove in any considerable degree detrimental to the affairs of Gustavus; the peasants from all parts of the kingdom flocked to his camp, and he was joined by a reinforcement from Lubeck. Christian, unable to suppress the revolt, wreaked his vengeance on the mother and sisters of Gustavus, whom he put to death with the most excruciating torments. Several other Swedish ladies he caused to be thrown into the sea, after having imposed on them the inhuman task of making the facks into which they were to be inclosed. His barbarities served only to make his enemies more resolute. Gustavus having assembled the states at Waditena, he was unanimously chosen regent, the diet taking an oath of fidelity to him, and promising to assist him to the utmost. Having thus obtained the sanction of legal authority, he pursued his advantages against the Danes. A body of troops appointed to throw succours into Stockholm were totally cut in pieces; and the regent sending some troops into Finland, struck the Danes there with such terror, that the archbishop of Upsal, together with Slahog and Baldenacker the Danish governors, fled to Denmark. Christian received them but very coldly, apprehending that their flight might be prejudicial to his affairs; and in a short time the two governors were put to death, that the king might have an opportunity of charging them with being guilty of the cruelties which they had committed by his order. He then sent express orders to all his governors and officers in Finland and Sweden to massacre the Swedish gentry without distinction. The Swedes made reprisals for massacring all the Danes they could find; so that the whole country was filled with bloodshed and slaughter.

In the mean time Gustavus had laid siege to the towns of Calmar, Abo, and Stockholm; but Norby found means to oblige him to raise all of them with great loss. Gustavus, in revenge, laid siege to the capital a third time, and petitioned the regency of Lubeck for a squadron of ships and other succours for carrying on the siege. This was complied with, but on very hard conditions, viz. that Gustavus should oblige himself, in the name of the states, to pay 60,000 merks of silver as the expence of the armament; that, until the kingdom should be in a condition to pay that sum,

sum, the Lubec merchants trading to Sweden should be exempted from all duties on imports or exports; that all other nations should be prohibited from trading with Sweden, and that such traffic should be deemed illicit; that Gustavus should neither conclude a peace, nor even agree to a truce, with Denmark, without the concurrence of the regency of Lubec; and that in case the republic should be attacked by Christian, he should enter Denmark at the head of 20,000 men. Upon these hard terms did Gustavus obtain assistance from the regency of Lubec; nor did his dear-bought allies prove very faithful. They did not indeed go over to the enemy; but in a sea-fight, where the Danes were entirely in the power of their enemies, they suffered them to escape, when their whole force might have been entirely destroyed. This treachery had well nigh ruined the affairs of Gustavus: for Norby was now making preparations effectually to relieve Stockholm; in which he would probably have succeeded: but at this critical period news arrived that the Danes had unanimously revolted, and driven Christian from the throne; and that the king had retired into Germany, in hopes of being restored by the arms of his brother-in-law the emperor. On hearing this news, Norby retired with his whole fleet to the island of Göthland, leaving but a slender garrison in Calmar. Gustavus did not fail to improve this opportunity to his own advantage, and quickly made himself master of Calmar. Mean time Stockholm continued closely invested; but Gustavus thought proper to protract the siege until he should get himself elected king. Having for this purpose called a general diet, the first step was to fill up the vacancy in the senate occasioned by the massacres of Christian. Gustavus had the address to get such nominated as were in his interest; and of consequence the assembly was no sooner met, than a speech was made, containing the highest encomiums on Gustavus, setting forth in the strongest light the many eminent services he had done for his country, and concluding that the states would show themselves equally ungrateful and blind to their own interest if they did not immediately elect him king. This proposal was acceded to by such tumultuous acclamations that it was impossible to collect the votes; so that Gustavus himself acknowledged, that their affection exceeded his merit, and was more agreeable to him than the effects of their gratitude. He was urged to have the ceremony of his coronation immediately performed; but the king having some designs on the clergy, did not think proper to comply with their request, as he would have been obliged to take an oath to preserve them in their rights and privileges.—Indeed he had not been long seated on the throne before he incurred the displeasure of that body; for having large arrears due to the army, with several other incumbrances, Gustavus found it necessary to raise large contributions on the clergy. On this he was accused of avarice and hereby before the pope's nuncio. Gustavus took the proper methods for defending himself against these accusations; and in a short time after showed a great partiality for the doctrines of Luther, which by this time had been preached and been received by many people in Sweden. This embroiled him more than ever with the ecclesiastics; and it soon appeared, that either Gusta-

Vol. X.

vus must resign his throne, or the clergy some part of the power they had assumed. Matters were driven to extremities by the king's allowing the scriptures to be translated into the Swedish language. In 1526, the king, finding them entering into a combination against the reformists, went to Upsal, and publicly declared his resolution of reducing the number of oppressive Popish and idle monks and priests, who, under pretence of religion, fattened on the spoils of the industrious people. At last, taking advantage of the war between the pope and Charles V. of Spain, he declared himself to be of the reformed religion, and established it throughout his dominions; and at the same time, to humble the arrogance of the ecclesiastics, he gave the senators the precedence of them, and in many other respects degraded them from the dignities they formerly enjoyed. For some time the states hesitated at supporting the king in his work of reformation; inasmuch, that at last he threatened to resign the kingdom, which, he said, was doomed to perpetual slavery either to its temporal or spiritual tyrants. On this the states came into his measures, and retrenched the privileges of the ecclesiastics in the manner he proposed. Several disturbances, however, ensued. An impostor, who pretended to be of the family of Sture the former regent, having claimed the throne, the Dalecarlians revolted in his favour; but on the approach of a powerful army sent by Gustavus, they submitted to his terms. Soon after, Lutheran professors were established in every diocese; upon which a new rebellion ensued. At the head of this, was Thure Johanfon, who had married the king's sister. Several of the nobility joined him; and the king of Denmark also acceded to their cause, thinking, by means of these disturbances, to reunite the three kingdoms of Sweden, Denmark, and Norway, as they had formerly been. But Gustavus prevailed, and the rebels were obliged to take refuge in Denmark. A fresh accident, however, had like to have embroiled matters worse than before. The subsidy granted to the regency of Lubec was still due; and for the payment of it the states granted to the king all the useless bells of the churches and monasteries. The people were shocked at the sacrilege; and the Dalecarlians again betook themselves to arms. Intimidated, however, by the courage and vigorous conduct of the king, they again submitted, and were taken into favour. Tranquillity was not yet restored. Christian having established a powerful interest in Norway, once more made an attempt to recover his kingdoms, and was joined by the Dalecarlians; but being defeated by the Swedish forces, he was forced to return to Norway, where, being obliged to capitulate with the Danish generals, he was kept prisoner all his life.

In 1542, Gustavus having happily extricated himself out of all his troubles, prevailed on the states to make the crown hereditary in his family; after which he applied himself to the encouragement of learning and commerce. A treaty was set on foot for a marriage between his eldest son Eric and Elizabeth queen of England. The prince's brother, duke John, went over to England, and resided for some time at the court of London with great splendour. He returned, full of expectations of success; but bringing with him no sort of proofs in writings, his father soon perceived

that he had been the dupe of Elizabeth's superior policy. However, at last he allowed Prince Eric to go in person to England; but before he could embark, the death of Gustavus made him lay aside all thoughts of the voyage and marriage.

35
Gustavus dies, and is succeeded by Eric a weak and imprudent prince.

Gustavus Vasa died in 1560, and was succeeded by his son Eric XIV. The new king was a man possessed of all the exterior ornaments which give an air of dignity to the person; but he had neither the prudence nor the penetration of his father. He created the first nobility that were ever known in Sweden; which he had no sooner done than he quarrelled with them, by passing some acts which they thought derogatory to their honour and dignity. The whole course of his reign was disturbed by wars with Denmark, and disputes with his own subjects. In the former he was unfortunate, and towards the latter he behaved with the greatest cruelty. At last, by the torments of his own conscience, it is said, he run mad. He afterwards recovered his senses, but was thereupon dethroned by his brothers; of whom Duke John, who had been hitherto kept prisoner by Eric, succeeded him in the kingdom.

36
Eric deposed, and succeeded by his brother John.

This revolution took place in the year 1568, but with no great advantage to Sweden. Disputes about religion between the king and his brothers, and wars with Muscovy, threw matters into the utmost confusion. At last prince Sigismund, the king's son, was chosen king of Poland, which proved the source of much trouble to the kingdom. He was elected on the following conditions, viz. That there should be a perpetual peace between the states of Poland and Sweden; that, on the death of his father, prince Sigismund should succeed to the throne of Sweden; that, on urgent occasions, he might, with the consent of the states, return to Sweden; that he should maintain, at his own expence, a fleet for the service of Poland; that he should cancel a debt which had been long due from the crown of Poland to Sweden; that, with the consent of the states, he should build five fortresses on the frontiers of Poland; that he should have liberty to introduce foreign soldiers into the kingdom, provided he maintained them at his own expence; that he should not make use of Swedish counsellors in Poland; that he should have his body-guard entirely of Poles and Lithuanians; and that he should annex to Poland that part of Livonia now subject to Sweden. In 1590 king John died; and as Sigismund was at a distance, every thing fell into the utmost confusion: the treasury was plundered, and the wardrobe quite spoiled, before even duke Charles could come to Stockholm to take the administration into his hands until king Sigismund should return. This, however, was far from being the greatest disaster which befel the nation at this time. It was known that the king had embraced the Popish religion, and it was with good reason suspected that he would attempt to restore it upon his arrival in Sweden. Sigismund also was obliged, on leaving Poland, to promise that he would stay no longer in Sweden than was necessary to regulate his affairs. These circumstances served to alienate the minds of the Swedes from their sovereign even before they saw him; and the universal dissatisfaction was increased, by seeing him attended, on his arrival in Sweden in 1593, by Malaspina the pope's nuncio,

38
Succeeds to the crown of Sweden.

to whom he made a present of 30,000 ducats to defray the expences of his journey to Sweden.

Sweden.

What the people had foreseen was too well verified: the king refused to confirm the Protestants in their religious privileges, and showed such partiality on all occasions to the Papists, that a party was formed against him; at the head of which was duke Charles his uncle. Remonstrances, accompanied with threats, took place on both sides; and at an interview between the king and Charles, the dispute would have ended in blows, had they not been parted by some of the nobility. This, however, made such an impression upon Sigismund, that he was apparently reconciled to his brother, and promised to comply with the inclinations of the people in every respect, though without any inclination to perform what he had promised. The agreement, indeed, was scarce made, before Sigismund conceived the horrid design of murdering his uncle at the Italian comedy acted the night after his coronation. The duke, however, having notice of the plot, found means to avoid it. This enraged the king so much, that he resolved to accomplish his designs by force; and therefore commanded a Polish army to march towards the frontiers of Sweden, where they committed all the ravages that could be expected from an enraged and cruel enemy. Complaints were made by the Protestant clergy to the senate: but no other reply was made them, than that they should abstain from these bitter invectives and reproaches, which had provoked the catholics, until the king's departure; at which time they would be at more liberty.

40
Forms a design of murdering his uncle.

In 1595 Sigismund set sail for Dantzic, leaving the administration in the hands of duke Charles. The consequence of this was, that the dissensions which had already taken place being continually increased by the obstinacy of the king, duke Charles assumed the sovereign power; Sigismund and in 1604 Sigismund was formally deposed, and his deposed, uncle Charles IX. raised to the throne. He proved a wife and brave prince, restoring the tranquillity of the kingdom, and carrying on a war with vigour against Poland and Denmark. He died in 1611, leaving the kingdom to his son, the celebrated Gustavus Adolphus.

47
Sigismund and his deposed, and is succeeded by Charles IX.

Though Charles IX. by his wife and vigorous conduct had in a great measure retrieved the affairs of Sweden, they were still in a very disagreeable situation. The finances of the kingdom were entirely drained by a series of wars and revolutions; powerful armies were preparing in Denmark, Poland, and Russia, while the Swedish troops were not only inferior in number to their enemies, but the government was destitute of resources for their payment.

42
State of Sweden on the accession of Gustavus Adolphus.

Though the Swedish law required that the prince should have attained his 18th year before he was of age, yet such striking marks of the great qualities of Gustavus appeared, that he was allowed by the states to take upon him the administration even before this early period. His first act was to resume all the crown-grants, that he might be the better able to carry on the wars in which he was unavoidably engaged; and to fill all places, both civil and military, with persons of merit. At the head of domestic and foreign affairs was placed chancellor Oxenstiern, a person every way equal to the important trust, and the choosing of whom impressed mankind with the highest opinion of the young monarch's penetration and capacity.

43
He is allowed to assume the administration while yet a minor.

Sweden.

Sweden.

Soon after his accession, Gustavus received an embassy from James I. of Britain, exhorting him to make peace with his neighbours. This was seconded by another from Holland. But as the king perceived that the Danish monarch intended to take every opportunity of crushing him, he resolved to act with such vigour, as might convince him that he was not easily to be overcome. Accordingly he broke into Denmark with three different armies at once; and though the enemy's superiority at sea gave them great advantages, and the number of the king's enemies distracted his attention, he carried on the war with such spirit, that in 1613 a peace was concluded upon good terms. This war being finished, the king applied himself to civil polity, and made some reformatiions in the laws of Sweden. In 1615, hostilities were commenced against Russia, on account of the refusal of that court to restore some money which had been formerly lent them. The king entered Ingria, took Kexholm by storm, and was laying siege to Plescow, when, by the mediation of James I. peace was concluded, on condition of the Russians repaying the money, and yielding to Sweden some part of their territory. In this and the former war, notwithstanding the shortness of their duration, Gustavus learned the rudiments of the military art for which he soon became so famous. He is said indeed to have caught every opportunity of improvement with a quickness of understanding seemingly more than human. In one campaign, he not only learned, but improved, all the military maxims of La Gardie, a celebrated general, brought the Swedish army in general to a more steady and regular discipline than had formerly been exercised, and formed and seasoned an invincible body of Finlanders, who had afterwards a very considerable share in the victories of the Swedes.

Peace was no sooner concluded with Russia, than Gustavus was crowned with great solemnity at Upsal. Soon after this, Gustavus ordered his general La Gardie to acquaint the Polish commander Cioekowitz, that as the truce between the two kingdoms, which had been concluded for two years, was now expired, he desired to be certainly informed whether he was to expect peace or war from his master. In the mean time, having borrowed money of the Dutch for the redemption of a town from Denmark, he had an interview on the frontiers with Christian the king of that country. At this interview, the two monarchs conceived the utmost esteem and friendship for each other; and Gustavus obtained a promise, that Christian would not assist Sigismund in any designs he might have against Sweden. In the mean time, receiving no satisfactory answer from Poland, Gustavus began to prepare for war. Sigismund entered into a negotiation, and made some pretended concessions, with a view to seize Gustavus by treachery; but the latter having intimation of his design, the whole negotiation was changed into reproaches and threats on the part of Gustavus.

Immediately after this, Gustavus made a tour in disguise through Germany, and married Eleonora the daughter of the elector of Brandenburg. He then resolved to enter heartily into a war with Poland; and with this view set sail for Riga with a great fleet, which carried 20,000 men. The place was well fortified, and defended by a body of veterans

enthusiastically attached to Sigismund. A dreadful bombardment ensued; the streets were raked by the cannon, and the houses laid in ashes by the bombs; the moat was filled up, one of the half-moons taken by storm, and the strong fortrefs of Dunamund was reduced. The cannon having now effected a breach in another part of the walls, Gustavus resolved to make a general assault. For this purpose a flying bridge over the moat was contrived by his majesty; for tho' the ditch was filled with fascines and rubbish, it still contained too much water to admit the passage of a large body of men. The soldiers, however, crowded on to the attack with so much impetuosity, that the bridge gave way, and the attempt proved unsuccessful. Next day the Swedes were repulsed in attempting to storm another half-moon; and the king was obliged to proceed more slowly. By the middle of September, at which time the town had been invested for six weeks, two bridges were thrown over the river together with a strong boom, while the Swedes had formed their mines under the ditch. The garrison being now reduced to extremity, were obliged to capitulate; and Gustavus treated the inhabitants with great clemency.

After the reduction of Riga, the Swedish monarch entered Courland, where he reduced Mittau; but ceded it again on the conclusion of a truce for one year. Sigismund, however, no sooner had time to recover himself, than he began to form new enterprises against the Swedes in Prussia; but Gustavus setting sail with his whole fleet for Dantzic, where the king of Poland then resided, so broke his measures, that he was obliged to prolong the truce for another year. Sigismund, however, was not yet apprised of the danger he was in, and refused to listen to any terms of accommodation: upon which Gustavus entering Livonia, defeated the Polish general, and took Derpt, Hockenhafen, and several other places of less importance; defeated, after which, entering Lithuania, he took the city of Birsen.

Notwithstanding this success, Gustavus proposed peace on the same equitable terms as before; but Sigismund was still insatuated with the hopes that, by means of the emperor of Germany, he should be able to conquer Sweden. Gustavus finding him inflexible, resolved to push his good fortune. His generals Horn and Thurn defeated the Poles in Semigalia, again defeated Gustavus himself with 150 ships set sail for Prussia, and where he landed at Pillaw. This place was immediately delivered up to him; as were also Braunfberck, Frawenberg, Elbing, Marienberg, Mew, Dirschau, Stnm, Christburg, &c. Sigismund, alarmed at the great successes of Gustavus, sent a body of forces to oppose him, and to prevent Dantzic from falling into his hands. In this he was attended with as bad success as before. His troops were defeated before Marienberg, Mew, and Dirschau; and in May 1627, Gustavus arrived with fresh forces before Dantzic, which he would probably have carried, had he not been wounded in the belly by a cannon-shot. The Poles in the mean time recovered Mew; and the States of Holland sent ambassadors to mediate a peace between the two crowns. Sigismund, however, depending upon the assistance of the emperor of Germany and king of Spain, determined to hearken to no terms,

and resolved to make a winter-campaign; but Gustavus was so well entrenched, and all his forts were so strongly garrisoned, that the utmost efforts of the Poles were to no purpose (A). The city of Dantzic in the mean time made such a desperate resistance as greatly irritated Gustavus. In a sea-engagement the Swedish fleet defeated that of the enemy; after which Gustavus, having blocked up the harbour with his fleet, pushed his advances on the land-side with incredible vigour. He made a surprising march over a morass 15 miles broad, assisted by bridges of a peculiar construction, over which he carried a species of light cannon invented by himself. By this unexpected manœuvre he got the command of the city in such a manner, that the garrison were on the point of surrendering, when, by a sudden swell of the Vistula, the Swedish works were ruined, and the king was obliged to raise the siege. In other respects, however, the affairs of Gustavus went on with their usual good fortune. His general Wrangel defeated the Poles before Brodnitz, of whom 3000 were killed, and 1000 taken prisoners, with five pieces of cannon and 2000 waggon loads with provisions. At Stum the king gained another and more considerable victory in person. The emperor had sent 5000 foot and 2000 horse under Arnheim, who joined the main army commanded by the Polish general Coniecpolski, in order to attack the Swedish army encamped at Quidzin. The enemy were so much superior in number, that the friends of Gustavus represented to him the imminent danger of attacking them. But the king being determined, the engagement began. The Swedish cavalry charged with such impetuosity, contrary to their sovereign's express order, that they were almost surrounded by the enemy; but Gustavus, coming up to their assistance, pushed the enemy's infantry with so much vigour, that they gave way, and retreated to a bridge they had thrown over the Werder. But here they were disappointed; for the Swedes had already taken possession of the bridge. On this a new action ensued more bloody than the former, in which the king was exposed to great danger, and thrice narrowly escaped being taken prisoner; but at last the Poles were totally defeated, with the loss of a great many men, 22 pair of colours, five standards, and several other military trophies. The slaughter of the German auxiliaries was so great, that Arnheim scarce carried off one half of the troops he brought into the field. This defeat did not hinder the Polish general from attempting the siege of Stum; but here again he was attended by his usual bad fortune. The garrison sallied out, and he was defeated with the loss of 4000 men. The blame of this misfortune was laid upon Arnheim; who was recalled, and succeeded by Henry of Saxe Lawenburg and Philip count Mansfeldt. The change of general officers, however, produced no good consequences to the Poles; a fa-

mine and plague raged in their camp, so that they were at last obliged to consent to a truce for six years, to expire in the month of June 1635. The conditions were, that Gustavus should restore to Sigismund the towns of Brodnitz, Stum, and Dirschau; that Marienberg should remain sequestered in the hands of the elector of Brandenburg, to be restored again to Sweden in case a peace was not concluded at the end of the six years. Gustavus, on his side, kept the port and citadel of Memel, the harbour of Pillau, the town of Elbing, Brunsberg, and all that he had conquered in Livonia.

Gustavus having thus brought the war with Poland to an honourable conclusion, began to think of restoring the conduct of the emperor in assisting his enemies and oppressing the Protestant states. Before embarking in such an important undertaking, it was necessary that he should consult the diet. In this the propriety of engaging in a war with Germany was warmly debated; but, after much altercation, Gustavus in a very noble speech determined the matter, and set forth in such strong terms the virtuous motives by which he was actuated, that the whole assembly wept and every thing was granted which he could require.

It was not difficult for Gustavus to begin his expedition. His troops amounted to 60,000 men, hardened by a succession of severe campaigns in Russia, Finland, Livonia, and Prussia. His fleet exceeded 70 sail, carrying from 20 to 40 guns, and manned with 6000 mariners. Embarking his troops, he landed at Usedom on the 24th of June 1630, the Imperialists having evacuated all the fortresses they possessed there; and the isle of Rugen had been before reduced by general Lelzy, in order to secure a retreat if fortune should prove unfavourable. Passing the frith, Gustavus stormed Wolgast and another strong fortress in the neighbourhood, leaving general Banner with a garrison for the defence of these conquests. He then proceeded to Stetin, which was no sooner invested than it consented to receive a Swedish garrison, and the king persuaded the duke of Pomerania to enter into an alliance with him. In consequence of this the Swedish troops were received into several towns of Pomerania; and the most bitter enemy took place between the Imperialists and Pomeranians, each refusing the other quarters.

These successes of Gustavus struck the empire with consternation; for being already overwhelmed with civil dissensions, they were in no condition to resist so impetuous an enemy. At this time also the Imperialists were without a general, the command of the army being disputed by a number of candidates of very unequal merit; but at last count Tilly was fixed upon as the most proper person, and invested with the dignity of Field Marshal. In the mean time the king, being reinforced by a considerable body of troops in

or.

(A) In this campaign the practice of duelling became so prevalent in the Swedish army, as to engage the king's attention, and to oblige him to suppress it by very rigorous edicts. Soon after these were passed, a quarrel arose between two general officers, who asked his majesty's permission to decide their difference by the laws of honour. The king consented, and wished to be a spectator of their courage. He went to the place appointed, attended by a body of guards: and having ordered the executioner to be called, "Now gentlemen, said he to the officers, fight until one dies;" adding to the executioner, "Do you immediately cut off the head of the other." On this the quarrel was dropped, and no more challenges were heard of in the camp.

vus.

Finland and Livonia under the conduct of Gustavus Horn, defeated the Imperialists before Griffenhagen; taking the place soon after by assault. By this and some other conquests he opened a passage into Lusatia and Silesia; but in the mean time count Tilly cut off 2000 Swedes at New Brandenburg, owing to the obstinacy of their commander Knipphausen, who had orders to evacuate the place and join the main army. This advantage, however, was soon overbalanced by the conquest of Frankfort on the Oder, which Gustavus took by assault, making the whole garrison prisoners. Thus he commanded the rivers Elbe and Oder on both sides, and had a fair passage not only to the countries already mentioned, but also to Saxony and the hereditary dominions of the house of Austria. Soon after this, Gustavus laid siege to Landsberg, which he took by assault; though the number of soldiers he had with him was so inconsiderable, that he had thoughts of sending to the main army for a reinforcement before the prisoners should march out, being apprehensive that they might give him battle in the open field, though they could not defend themselves behind walls.

62
He reduces
Pomerania,
and restores
the dukes of
Mecklen-
burg.

About this time the Protestant princes held a diet at Leipzig; to which Gustavus sent deputies, and conducted his negotiations with such address, as tended greatly to promote his interests. Immediately after this he reduced Gripswald, and with it all Pomerania. Then marching to Gultrow, he restored the dukes of Mecklenburg to their dominions. Here the Imperialists had tyrannized in such a manner that Gustavus was received as the deliverer of the people, and the ceremony of the duke's inauguration was in a short time performed with great solemnity.

63
Magdeburg
taken by the
Imperialists,
and the inhabi-
tants cruel-
ly used.

All this time count Tilly was employed in the siege of Magdeburg; but now, being alarmed at the repeated successes of the Swedes, he left Pappenheim with part of the army before that city, while he marched with the rest into Thuringia, to attack the landgrave of Hesse-Cassel and the elector of Saxony.

After a most obstinate defence, Magdeburg fell into the hands of Pappenheim, where he committed all imaginable cruelties. Gustavus formed a plan of recovering the city; but was obliged to abandon it, by Pappenheim's throwing himself into the place with his whole army, and by the progress which Tilly was making in Thuringia. Relinquishing this enterprise, therefore, he ordered Banner to attack Havelsburg; which was done with such resolution, that the place was forced in a few hours, and all the garrison made prisoners. Werben was next obliged to submit after an obstinate conflict, in which many fell on both sides.

64
Havelsburg
and Wer-
hen re-
duced, and
the cavalry
of the Im-
perialists
defeated by
the Swedes.

—These successes obliged count Tilly to attempt in person to check the progress of the Swedes. He detached the vanguard of his army, composed of the flower of the Imperial cavalry, within a few miles of the Swedish camp. An action ensued, in which Bernstein the Imperial general was defeated and killed, with 1500 of his men. Gustavus, after this advantage, placed himself in a situation so much superior to his enemies, that count Tilly was fired with indignation, and marched up to the Swedish lines to give him battle. Gustavus kept within his works, and Tilly attacked his camp, though almost impregnable fortified, keeping up a most terrible fire from a battery of 32 pieces of

cannon; which, however, produced no other effect, than obliging the Swedish monarch to draw up his army behind the walls of Werben. Tilly had placed his chief hopes in being able to nail up the enemy's cannon, or set fire to their camp in divers quarters; after which he proposed making his grand attack. With this view he bribed some prisoners; but they betrayed him, and told his design to Gustavus. The king ordered fires to be lighted in different parts of his camp, and his soldiers to imitate the noise of a tumultuous disorderly rabble. This had the desired effect. The count led his army to the breach made by the cannon; where he was received with such a volley of grape-shot as cut off the first line, and put the whole body in disorder, so that they could never be brought back to the charge. In this confusion the Imperial army was attacked by Bauditz, and, after an obstinate conflict, obliged to quit the field.

Soon after this action the queen arrived at the camp with a reinforcement of 8000 men; at the same time a treaty was concluded with Charles I. of England, by which that monarch allowed the marquis of Hamilton to raise 6000 men for the service of Gustavus. These auxiliaries were to be conducted to the main army by a body of 4000 Swedes; and were in every thing to obey the king while he was personally present, but in his absence were to be subject to the orders of the marquis. With these troops the king had resolved to make a diversion in Bremen; but the marquis finding it impossible for him to effect a junction with the Swedish army, resolved, without debarking his troops, to steer his course for the Oder, and land at Usedom. Gustavus was very much displeased at finding his project thus disconcerted; however, making the best of the present circumstances, he commanded the British troops to act on the Oder instead of the Weser. The number of this little army was magnified exceedingly by report, inasmuch that count Tilly had some thoughts of marching against them with his whole force; but on the departure of the marquis for Silesia, he reinforced the army in that country with a large detachment, which was thought to contribute not a little to the defeat he soon after received.

Ever since the late action Gustavus had kept within his intrenchments, where his army was well provided with every thing. Tilly made several attempts to surprise or draw him to an engagement; but finding all his endeavours fruitless, he marched into Saxony, and laid siege to Leipzig. This precipitate measure proved highly advantageous to the Swedish monarch; as thus the elector, who had been wavering in his resolutions, was now obliged to have recourse to the Swedes, in order to preserve himself from utter destruction. A treaty offensive and defensive was immediately concluded with Gustavus: and the elector willingly promised every thing that was required of him; and among the rest, that not only the prince his son, but he himself, should reside in the Swedish camp, and engage his life and fortune in the common cause. Tilly, in the mean time, carried fire and sword into the unhappy electorate. At the head of an army of 44,000 veterans, he summoned the city of Leipzig to surrender; denouncing the same vengeance against it as had been executed on Magdeburg, in case of a refusal. By this the governor was so much intimidated, that he instant-

Leipfic.

ly submitted; and also surrendered the castle of Paffenberg, which was in a condition to have stood out till the arrival of the Swedish army. The elector, enraged at the loss of these valuable places, ordered his army to join the Swedes with all expedition, and pressed the king to warmly to engage, that at last he yielded to his desire. On the 7th of September 1631, Gustavus led out his army in the most beautiful order, the Swedes forming one column on the right, and the Saxons another on the left; each amounting to 15,000 men. Tilly drew up his men in one vast column, possibly with a view of surrounding the flanks of the king's army; but every officer of experience in his army, from the excellency of the Swedish disposition, prognosticated the event of the engagement. Gustavus led on the troops against that wing of the Imperialists commanded by Pappenheim, whom he drove back to such a distance, that he gained a point of the wind; by which the smoke fell upon their enemies and considerably embarrassed them, at the same time that the Swedes were got without the reach of a battery which played furiously on their flank. General Banner in the mean time cut in pieces the troops of Holstein, and mortally wounded the duke who commanded them. Pappenheim led on his troops seven times to the charge, in hopes of regaining his former situation; but was as often repulsed by the Swedes. Tilly all this while was engaged with the Saxons; but having at last driven them off the field, the whole strength of the Imperial army was turned upon the Swedish left wing commanded by General Horn. The Swedes sustained the attack with the greatest firmness, until the king detached general Teuffel with the centre to assist them. The Imperialists then were no longer able to stand their ground; but gave way every where except in the centre, which was composed of 18 regiments of veterans accustomed to victory, and deemed invincible. They made incredible efforts to maintain the reputation they had acquired; and, though swept off in great numbers by the Swedish artillery, never shrunk or fell into confusion. Four regiments, after their officers had been killed, formed themselves, and retired to the skirt of a wood; where they were all to a man cut in pieces, without demanding quarter. Tilly retired at the head of 600 men, and escaped by the coming on of the night. Seven thousand Imperialists lay dead on the field of battle; 4000 were taken prisoners; a fine train of artillery was lost, with upwards of 100 standards, ensigns, and other military trophies.—On this occasion it was that the Scots regiment in the Swedish service first practised the method of firing in platoons; to which some ascribe the astonishment and confusion that appeared in the Imperial army. It is thought, however, that the Swedish monarch displayed greater abilities in gaining this victory than improving it afterwards; for had he marched immediately to Vienna, before his enemies had time to recover their consternation, it is supposed that the emperor would have been obliged to abandon his capital, and leave his hereditary dominions to the mercy of the conqueror. But Gustavus apprehended that Tilly might fall upon the Saxons while he was ravaging the Austrian hereditary dominions; which would have deprived him not only of an ally, but of the free quarters which the elector had promised to his troops in case of a retreat.

69
The Imperialists defeated with great slaughter.70
Conduct of Gustavus censured.

For this and some other reasons he determined to penetrate into Franconia, where he reduced several places, particularly the fortrels of Workburg. Tilly, having collected his scattered troops, which formed an army still superior in number to that of Gustavus, marched to the relief of this place; but came too late. He then directed his march towards Rottenberg, where four regiments were cut in pieces by a Swedish detachment. After this the king reduced Hanau, Franckfort on the Maine, and Mentz; destroying a body of Spaniards, who had thrown themselves in his way to obstruct his passage.

The court of Vienna was now thrown into the utmost confusion; and sent every where begging assistance, and soliciting the Catholic princes to arm in defence of their religion. The emperor was most embarrassed in finding out a general capable of opposing Gustavus in the field; for the late misfortunes of count Tilly had entirely sunk his reputation. Wallestein, an old experienced officer, was made choice of; but as he had formerly been disgraced, it was apprehended that he would not accept of the command of which he had once been deprived. This objection, however, was got over; and Wallestein not only accepted of the command, but, at his own expence, augmented the army to 40,000 men.

During the whole winter the Swedish army kept the field; and before the approach of summer had reduced Crantzach, Bobenhafen, Kirchberg, Magdeburg, Gozlar, Northeim, Gottingen, and Dunderstadt; while the landgrave William made great progress in Westphalia. Gustavus Horn was repulsed before Bamberg; but soon had his revenge, by entirely destroying two regiments of Imperialists. To prevent the troops from being affected by the loss before Bamberg, the king resolved to give battle to Tilly, who was marching into Bavaria to prevent the Swedes from gaining a footing in that electorate. He pursued the Imperial general through a vast tract of country, defeated his rear-guard, and, having reduced a variety of towns and fortresses on the Danube, penetrated as far as Ulm. Advancing to the river Leck, count Tilly posted himself in a wood on the opposite side, to dispute his passage. Gustavus endeavoured to dislodge him by a regular fire from 70 pieces of cannon. The slaughter was dreadful; and Tilly himself, being wounded by a cannon-ball in the knee, died a few days before he was to have been superseded by Wallestein. The following night the Imperial army evacuated the post; part retiring to Ingoldstadt, and others to Neuburg. Gustavus immediately crossed the river, and seized the towns of Rain and Neuburg, which the enemy had abandoned. Augsborg next submitted; and from the inhabitants of this place Gustavus exacted an oath of fidelity, not only to himself but to the crown of Sweden. This measure gave the greatest offence to many of the Germanic body, and made them imagine that the king of Sweden had other views than the defence of the Protestant cause.

From Augsborg the Swedes advanced towards Ratibon; but were disappointed in their design of getting possession of that city by reason of the Bavarians having thrown a very numerous garrison into the place.—In the mean time ambassadors arrived from Denmark, offering the mediation of that crown for obtaining

a lasting peace between the contending powers. Gustavus, however, replied, that no such peace could take place till the Catholic princes thought proper to grant the Protestants full and ample security for their enjoyment of future tranquillity. But the ambassadors had no instructions to propose any thing farther; and thus the negotiation vanished. Gustavus now, resolving to retort upon themselves the cruelties which the Bavarians had inflicted on the Protestants, laid the towns of Morzburg, Friefengen, and Landshut, in ashes. The inhabitants of Munich saved their city by submission; but, as the peasants in that neighbourhood had collected themselves into bodies in order to murder the stragglers from the Swedish army, Gustavus burnt their houses, and defeated the forces of the elector, who had been joined by a considerable body of militia.

While Gustavus was thus employed, Wallenstein had assembled a vast army. He was strongly solicited by the elector of Bavaria to come to his assistance; but, in revenge of the electors having formerly obtained the command for count Tilly in preference to himself, he drew off towards Bohemia to encounter the Saxons. Arnheim, who commanded the Saxon forces in that place, was the enemy of Gustavus, who had formerly rallied him for his cowardice. He therefore permitted Wallenstein to gain an easy victory, in hopes that his master the elector of Saxony, a prince entirely devoted to his pleasures, might be induced to relinquish the friendship of such a restless and warlike ally as Gustavus; with whom indeed he used all the eloquence of which he was master, to detach him from the Swedish cause. Several advantages in the mean time were gained by the Imperialists. Pappenheim defeated the archbishop of Bremen's cavalry at Werden; and three Swedish regiments were cut off near Kadingen. Pappenheim, however, was forced to retire, and withdraw his garrison from Stade; of which the Swedes took possession. Wallenstein and the elector of Bavaria, who had now joined their forces, threatened Gustavus with greatly superior numbers. At last, however, the king, being reinforced with 15,000 men, no longer declined the engagement; but Wallenstein was too wise to trust the fate of the empire to a single engagement against such an enemy as the king of Sweden. Gustavus attacked his camp, but was repulsed with the loss of 2000 men; which caused a general murmuring and discontent against his rashness. Several other misfortunes happened to the Swedes; and at last, after various manœuvres, Wallenstein bent his course towards Misnia, in order to oblige the elector of Saxony to declare against the Swedes, and to draw them out of Bavaria. Gustavus, notwithstanding the inconstancy of Augustus, immediately set out to assist him. With incredible diligence he marched to Misnia, where the Imperialists were assembling their whole strength. Hearing that the enemy were encamped at Weisenfels, and that Pappenheim had been detached with a strong corps, Gustavus resolved to engage them before they could effect a junction. With this view he marched to Lutzen, where he attacked Wallenstein with incredible fury. The Swedish infantry broke the Imperialists in spite of their utmost efforts, and took all their artillery. The cavalry not being able to pass the river so expeditiously as the king thought necessary, he led the way, attended only by the regiment

of Smaaland and the duke of Saxe-Lawenburg. Here, after charging impetuously, he was killed, as Puffendorf alleges, by the treachery of the duke; who, being corrupted by the emperor, shot him in the back during the heat of the action. The news of his death was in an instant spread over both armies. The courage of the Imperialists revived, and they now made themselves sure of victory. But the Swedes, eager to revenge the death of their beloved monarch, charged with such fury that nothing could resist them. The Imperialists were defeated a second time, just as Pappenheim, with his fresh corps, came up to their assistance. On this the battle was renewed, but the Swedes were still irresistible. Pappenheim was mortally wounded, and his army finally routed, with the loss of 9000 killed in the field and in the pursuit.

The victory of Lutzen proved more unfortunate to Sweden than the greatest defeat. The crown devolved upon Christina, an infant of six years old; the nation was involved in an expensive foreign war, without any person equal to the arduous task of commanding the armies, or regulating domestic affairs, as Gustavus had done. However, Christina, the daughter of Gustavus, was immediately proclaimed queen. The regency devolved on the grand bailiff, the marshal, the high admiral, the chancellor, and the treasurer of the crown. Oxenstiern was invested with the chief management of affairs, and conducted himself with the greatest prudence. He was greatly embarrassed indeed by the divisions among the Protestant princes, which became more violent after the death of Gustavus; but, in spite of all difficulties, he went on pursuing the interest of his country, and planning the means of retaining the Swedish conquests. Matters went on pretty successfully till the year 1634, when, through the rashness of the Swedish soldiers, they were defeated at Nordlingen, with the loss of 6000 men killed on the spot, a number of prisoners, and 130 standards with other military trophies, taken by the enemy. Oxenstiern's constancy was shaken by this dreadful blow; but he applied himself diligently to repair the loss, by recruiting the army, and rendering the allies faithful. The latter proved the most difficult task. The death of Gustavus, and the defeat at Nordlingen, had thrown them into despair; and every one was desirous of making the best terms he could with the emperor. The Saxons not only renounced their alliance with Sweden, but openly commenced war against it; and the regency would gladly have consented to an honourable peace, the enemy were now too much flushed with success to grant it. Oxenstiern had no other resource than an alliance with France, and the bravery of his generals. In 1635, he went in person to the court of Lewis, and concluded a treaty; which, however, answered no purpose, as it was never observed. The enemy, in the mean time, pushed their good fortune. They surprised Philippsburg, where the French had laid up vast magazines; and reduced Spire, Augsbourg, Treves, Wurtzburg, Coburg, and some other places. To complete the misfortunes of Sweden, it was expected that the Poles would immediately invade Prussia. To prevent this, La Gardie was dispatched thither with a powerful army; but as it was impossible to resist so many enemies at once, the chancellor purchased the friendship of Poland for 26 years by ceding that duchy to the republic. Thus

Sweden. he got rid of a powerful enemy; and the Swedish affairs began to revive by a victory which general Bannier gained over the Saxons, in consequence of which they were driven beyond the Elbe.

85 The Saxons defeated by general Bannier. Early in the spring of 1636, the Saxons made some motions as if they intended to cut off Bannier's communication with Pomerania. This he prevented by a stratagem; defeated a body of the enemy, and obliged the Saxons to retire. Soon after this he drove them out of their winter-quarters with considerable loss, at which time also a considerable body of Imperialists who came to their assistance were dispersed. In Westphalia general Kniphausen beat the Imperialists with the loss of 1500 men; but he himself was killed in the pursuit, and his army obliged to repossess the Weser. Some advantages were also gained in the neighbourhood of Minden by general Lessly who had assembled a considerable army. In Alsace, Bernard duke of

87 And by the duke of Saxe-Weymar. Saxe-Weymar defeated count Gallas the Imperial general, and dispersed his army. But when every thing seemed thus successful for the Swedes, the city of Magdeburg, contrary to the expectation of every body, surrendered for want of powder, which the garrison had wantonly consumed. The Saxons also made some conquests on the Elbe, which obliged Bannier to recall general Lessly from Westphalia to march against them. The Saxons fixed on a most convenient situation, whence they hoped to destroy the Swedish army without coming to a battle. But Bannier, resolving to hazard every thing rather than suffer his army to be wasted by famine, advanced towards Perleberg, a place closely blocked up by the enemy. Here he drove from an advantageous post four regiments of Saxon cuirassiers, having killed or taken prisoners 400 men; after which he soon forced them to a general engagement. The numbers were very unequal, Bannier's army amounting to 9000 horse and 7000 foot, and the Saxons to 15,000 horse and 13 battalions of foot. The battle began with great fury; the right wing of the Swedes was almost oppressed by numbers before the left could come to their assistance. They were ten times driven back, and as often returned to the charge. At the last time they made such a desperate effort, that the enemy were entirely broken and defeated. Five thousand were killed on the spot, 3000 wounded, and as many taken prisoners, together with 150 colours and standards, and several pieces of cannon.

88 The Saxons entirely defeated by Bannier. Thus ended the campaign of 1636, in a manner highly honourable to the Swedes. Some fruitless negotiations were set on foot during the winter; but these coming to nothing, Bannier quitted his winter-quarters very early in the season; and falling upon eight regiments of Saxons cantoned at Eulenburg, pursued them to Torgau, where he obliged them to surrender at discretion. Another party of Saxons was defeated in the neighbourhood of Leipzig; after which he proposed investing that city. But in this project he was disappointed by the Imperialists penetrating into Thuringia. He then called in all his detachments, with a view to prevent them from crossing a river named *Sala*; but in this also he was disappointed; however, he had the good fortune to defeat 2000 imperialists near Pegau, and destroy several detachments that attempted to obstruct his march.

Sweden. Yet, notwithstanding all these successes, Bannier found his situation every day more straitened, from the continual increase of the enemy's forces; which obliged him at last to retreat into Pomerania, out of which he soon drove out count Gallas.

The affairs of the Swedes were now once more reduced to the brink of ruin through the unguarded conduct of General Wrangel, who had also an army in Pomerania. After Bannier had driven count Gallas out of the province as above-mentioned, Wrangel, imagining himself perfectly secure, cantoned his troops and extended his quarters, the better to accommodate his army. But Gallas being informed of this proceeding, suddenly returned, ravaged all Upper Pomerania, and reduced the towns of Ustedom, Dornmin, and Wollin; after which, leaving garrisons in the fortresses, he returned to his winter-quarters in Saxony.

This unfortunate campaign counterbalanced all the advantages of the former. Wrangel was so struck with the suddenness of the blow, that he could take no measures for opposition. Some of the Swedish allies again fell off, and took up arms against them. In 1638, the Swedish affairs again began to revive in this quarter, through the excellent conduct of Bannier, who defeated count Gallas with the loss of 3000 men killed and taken prisoners. Pursuing his good fortune, he so harassed the count, that he obliged him in great haste to repossess the Elbe, and take shelter in the hereditary dominions of Austria. Great as Bannier's exploits had been, however, they were eclipsed by those of duke Bernard. That general had so increased his army in the Protestant cantons of Switzerland, and in Franche Comte, that he found himself in a condition to act without the assistance of the French, who indeed were but treacherous allies. Advancing to the Rhine, he seized on Seckingen and Laßburg, and laid siege to Rheinfeld. The Imperialists, in conjunction with the troops of Bavaria, advanced to the relief of the place. An engagement ensued; in which the victory was disputed: the enemy threw succours into the city, and the duke withdrew his army. Within a month he gave them battle a second time; and so completely defeated them, that only one Imperial officer above the rank of a captain escaped being killed or taken prisoner. He then renewed the siege of Rheinfeld; which he reduced, as well as several other important places. Advancing to Brisach, he blocked it up with a design of forcing the garrison to surrender by famine. General Gotz, with 12,000 men, attempted to throw in 1000 waggons of provision; but he was defeated, with the loss of all his men except 2500. Duke Charles of Lorraine, with 4000 men, joined the remains of Gotz's army, in order to relieve the town; but being surprised by Bernard, his whole army was cut in pieces. A third attempt was made by Gotz, but it proved as unsuccessful as the former; and the place being reduced to great straits, was obliged to capitulate.

In January 1639, the two victorious generals Bernard and Bannier prepared to attack the enemy on their own ground. Bannier made an irruption into the territories of Anhalt and Halberstadt. Leaving his infantry behind, he pushed on with his cavalry, and surprised Salis, grand-master of the Imperial artillery.

gagements.

tilery. After a bloody conflict, the Swedes gained a complete victory, seven regiments of the enemy being cut in pieces. Next entering Saxony, he defeated four regiments of the enemy, obliging a much larger body to take shelter under the cannon of Dresden. Hearing that the Saxons were encamped near Chemnitz, where they waited to be joined by the Imperialists, he resolved to attack them before this junction could be effected. The same good fortune still attended his arms, and the Saxons were almost all killed or taken. Banner next entering into Bohemia, laid the country under contribution; after which, returning cross the Elbe, he fell on general Hofskirk, who was encamped near Brandeiz with 10 regiments of horse and several battalions of foot. Him he defeated with the loss of 2000 men. The remains of the Imperial forces were pursued to the walls of Prague, and the generals Hofskirk and Montecuculi were taken prisoners. Yet, notwithstanding these constant successes, the enemies of Banner multiplied daily. He had expected an insurrection in his favour in Silesia or Bohemia; but no such event took place. The Protestant princes, overawed by the enemy, did not send him the necessary assistance. Undismayed, however, by difficulties or danger, Banner performed wonders. He defeated a body of Imperialists at Glatz: three times he drove the Saxons from their camp at Firn; and yet was forced to evacuate the place, because he could not spare a garrison. His army being destitute of the means of recruiting, was considerably diminished in number; yet with it he reduced a number of towns, and obtained a variety of other important advantages, when on a sudden all his hopes were blasted by the death of the duke of Saxe-Weymar; poisoned, as was supposed, by the French, who were desirous of getting the town of Brisac into their hands, from which the duke prevented them.

95
Death of the
duke of Saxe-
Weymar.

96
Treachery
of the
French.

The difficulties to which Banner was now reduced proved extreme. The French monarch took upon him to dispose of the army and conquests of Bernard as he thought proper. Brisac, and other places of importance, he kept to himself; after getting possession of which, the French endeavoured, as much as possible, to ruin the army. In the mean time the Imperial army under Piccolomini, in the Netherlands, was prodigiously augmented; and the archduke Leopold-William, in quality of generalissimo, was assembling his whole strength to crush the Swedes at once. Banner, however, did not despair. George duke of Lunenburgh having conceived some disgust at the emperor, Banner hoped to gain him over; he therefore approached nearer to his country; by which also he drew towards the armies of Weymar and Hesse. In his way he cut in pieces a body of 3000 Croats. General Konigsmark routed the Imperialists at Gera; a second time at Scholen; and a third time entirely defeated them near Leipzig. Banner was very pressing on the allies to join him; and at last, in 1640, he was joined by the Weymar army under the dukes of Longueville and Gubrien, a body of Russians led by general Melander, and the troops of Lunenburgh commanded by general Klitzing. The army now amounted to 22 battalions of infantry and 22,000 horse; so that they were much more than a match for their enemies, had they been under the sole direction

ists defeated
by Konigsmark.

of Banner. But unanimity was wanting; every one would be supreme in the command; and Banner, the best general of them all, had the least influence. Instead of those mastery and decisive strokes by which the Swedes had hitherto distinguished themselves, the armies continued looking at one another, each suffering the rigours of famine. At last Banner, resolving to expose his troops no longer, set out for Thuringia, through Franconia, to seize an advantageous post on the Maine; but as he advanced to the Sala, he found the Imperialists entrenched on the other side. Finding it impossible to force a passage, he took the road through Hesse, where his troops suffered greatly by famine. Here he proposed to fight the enemy; but the Landgrave and duke of Lunenburgh refused their consent. Upon this he threatened to leave them to the mercy of the confederates, and thus obliged them to be somewhat more pliant. None of those brilliant successes, however, now attended the operations of the Protestant allies: the campaigns of 1640 and 1641 were spent in useless marches and countermarches; serving only to bring the army into the greatest dangers, from which they were as constantly relieved by the active and intrepid Banner. At last this brave general, worn out with perpetual fatigues, died of a fever in the year 1641, leaving the Swedish army in a worse situation than ever.

98
Death of
Banner.

The Imperialists were too well acquainted with the abilities of Banner not to take advantage of the opportunity offered by his death. A Swedish detachment was cut in pieces at Quidlenberg. The Swedish army, accustomed only to be obedient to Banner, became mutinous, and Piccolomini resolved to fall upon them with his whole force. But the four generals, Wrangel, Konigsmark, Wittemberg, and Pihul, having convinced the soldiers of the necessity of defending themselves, made such excellent dispositions, that the Imperialists durst not attack them. Piccolomini then detached part of his army to attack the Hessians in their quarters; but Wrangel and Konigsmark threw themselves in their way, and defeated them with the loss of 2000 men. This victory, however, did not retrieve the Swedish affairs. Dissensions and mutiny began again to take place in the army to such a degree as threatened its dissolution. In 1642 General Torstenlen was sent from Sweden, with a large sum of money and a strong reinforcement, to take upon him the supreme command. This general was inferior in abilities to none of his predecessors, and despatched without loss of time to come to an engagement; but the Weymar army separating from him, put an end to that design, and obliged him to remain for a considerable time inactive. He was also confined to his chamber for some time by a dangerous gout; and thus a report of his death being spread, the Imperialists were encouraged to begin a long march through roads scarce passable, in hopes of surprising the Swedish army without a general. Torstenlen having intelligence of this, seized an advantageous post which could not be forced; and thus obliged the enemy to retreat, after having suffered as much by their fatiguing march as if they had fought a bloody battle. Then joining general Stalhanck, who had been driven by the Imperialists out of Silesia, he reduced the town of Glogau, with a number of other important places;

after which he laid siege to Schweidnitz. The duke of Saxe-Lawenburgh, at the head of all his cavalry, endeavoured to throw in fuccours; but was defeated with the loss of 3000 men. He himself was taken prisoner, and died of chagrin a few days after. In consequence of this defeat Schweidnitz surrendered at discretion; and Torstenson having sent a detachment to invest the city of Neisse, proceeded with the rest to drive the enemy entirely out of Silesia. This he effected actually performed; obliging them to retire over barren mountains, almost famished for want of provision, and harassed by his light troops; so that this lately formidable army was almost entirely ruined. With his victorious troops the Swedish general then poured into Moravia; where, in five days, he reduced the strong town of Olmutz (which not long ago sustained a siege of as many weeks by the king of Prussia.) Litta and Newstadt shared the same fate; after which the Swedes, returning suddenly to Silesia, made themselves masters of Oppelen, Brieg, and laid siege to Breslau. Here the garrison made such an obstinate defence, that the Imperialists had time to assemble under the conduct of the archduke Leopold, and come to their relief. As Torstenson was greatly inferior in number, he raised the siege; but appeared so formidable in his retreat, that the enemy durst neither attack him, nor attempt to prevent his encamping in a very advantageous situation. The Imperialists took this opportunity of laying siege to Glogau: but after having lost a great number of men, they were forced to abandon the enterprise on the junction of Wrangel with Torstenson; by which means the Swedes were once more in a condition to face their enemies in the field.

Torstenson now projected an irruption into Bohemia, and putting his army into winter-quarters in that country; but in this he was prevented by the vigilance of the enemy: however, he reduced the city of Zittau, where, for the first time, a cartel for prisoners was established; by which means the Swedish army was considerably augmented. Thus disappointed in his designs on Bohemia, Torstenson directed his course to Leipzig, which he intended to invest. The Imperial generals assembled their whole force, and set out to relieve that important place. The two armies soon came in sight of each other; and a furious cannonading was the prelude to a general engagement. A single bullet had almost proved fatal to the Swedish cause. It carried away the furniture of Torstenson's horse, killed the count Palatine's horse, pierced general Rabenau through the body, took off the head of a celebrated counsellor named *Gräbe*, and carried away the leg of a private soldier. The Swedes, as soon as the armies came up, behaved with their wonted resolution, and after an obstinate conflict obtained a complete victory; 5000 of the enemy being killed on the spot, 3000 wounded, and as many taken prisoners. This victory was followed by the immediate surrender of Leipzig; and in all probability the Swedes would have finally triumphed over all their enemies, had not a rupture with Denmark ensued. Torstenson and Horn behaved with their usual valour in Holstein and Schonen, while general Königsmark distinguished himself in Germany; but the ruin of the Weymar army, which was totally defeated with the

loss of one half its number at Dettingen by the Bavarians, proved a dreadful blow, from which the Swedes could scarce recover themselves. Indeed, notwithstanding the valour and success of the Swedes, their affairs in Germany must have gone to wreck in the campaigns of 1643 and 1644, had not the French under Conde and Turenne made a most powerful diversion, and performed such exploits as immortalized the names of these two generals.

In 1645, the war against Denmark was pushed with such vigour, that a peace, very honourable and advantageous for Sweden, was concluded; and thus Torstenson was again at liberty to act against the Imperialists. He now took measures for carrying the war into the heart of the Austrian dominions. Hatfield assembled a considerable army to oppose the Swedes; and the emperor came in person to Prague to animate his troops. The two armies came in sight at Jancowitz, and both prepared for an engagement. The valour of the Swedes once more prevailed; and they totally defeated their enemies. Four thousand of the Imperialists were killed on the spot, among whom were general Hatfield and a great number of officers; and near 5000 were taken prisoners. No great advantages, however, were derived from this victory. Some towns indeed were reduced; but at last Torstenson was obliged to retire into Moravia, where he put his army into winter-quarters; and in the beginning of the year 1646 resigned the command to Wrangel.

The new general conducted the Swedish affairs with great ability and success; till at last the Imperialists, finding themselves finally unable to drive the Swedes out of Germany, concluded a peace with them in 1648. This was the memorable treaty of Westphalia, by which the Germanic constitution was settled upon its ancient principles, and those implacable disputes which had long torn the empire were ended; the duchies of Bremen and Verden, all the Upper and part of Lower Pomerania, the city of Wismar and the isle of Rugen, were assigned to Sweden, and a gratification of five millions of crowns was given to the army.

Sweden now enjoyed some years of repose. Charles Gustavus, count Palatine, having gained the favour of Christina, was appointed generalissimo of the forces, heir to the and heir-apparent to the crown. A marriage was proposed between them; but the queen would never listen to this or any other proposal of the kind. In 1650, the ceremony of the queen's coronation was performed; but in four years thereafter, she resigned the crown in favour of Gustavus. (See the article *CHRISTINA*.)

The new king found himself involved in considerable difficulties on his accession to the throne. The treasury was quite exhausted; great part of the revenue was appointed for the support of Christina's household; the people were oppressed with taxes; and the nation having been disarmed for several years, began to lose its reputation among foreigners. To remedy these evils, Charles proposed to reimburse all the crownlands which had been alienated by grants to favourites during the late reign; to repeal a duty which had been laid upon salt; to put the kingdom in a posture of defence; and to enter upon a war with some neighbouring state. Under pretences, therefore, that Casimir king of Poland had questioned his title to the throne,

throne, he began to make preparations for invading that kingdom. Several embassies were sent from Poland to Stockholm; but some point of ceremony always disappointed them of an audience of the king; so that they were obliged to return without their errand. As soon as matters were in readiness, General Wittenberg made an irruption into Poland from the side of Pomerania. The Poles opposed him with an army of 15,000 men; but instead of fighting, they began to negotiate, and in a short time entirely dispersed themselves. Charles himself soon followed with a powerful army, and pursued his march without obstruction, all the cities throwing open their gates to him as he approached, and offering to supply him with necessaries. As he advanced to Cracow, Casimir resolved to make one effort to save his capital. His army amounted only to 10,000 men; and these were unfortunately such as had never stood fire. After a feeble resistance they fled with precipitation, having lost 1000 men killed and taken prisoners. A few days after this Charles defeated the Poles a second time about eight leagues from Cracow; upon which Casimir fled with his family to Oppelen in Silesia. The capital was then invested; and, though defended with the utmost valour by Stephen Czarneski, was in a short time obliged to capitulate. Thus in less than three months Charles apparently became master of Poland; but it soon became evident that the Poles had no intention of abandoning their former sovereign.

115
War with
the Elector
of Branden-
burg.

In 1656 a war took place with the elector of Brandenburg. While Charles was employed in the conquest of Poland, that prince had invaded the Royal and Ducal Prussia, and reduced the most considerable towns with little opposition. The king of Sweden took umbrage at his progress; and having marched against him, defeated his forces in several slight encounters, and obliged him to own that he was a vassal of Sweden. These rapid conquests alarmed all Europe; and the different powers sought for means of driving the Swedes out of Poland, which they had so unexpectedly and unjustly seized. The Poles were no sooner assured that they should be assisted, than they every where revolted and massacred the Swedes. Casimir returned from Silesia; and those very troops and generals who had before submitted to Charles without opposition, now ranged themselves under the banners of his antagonist. Charles immediately marched from Prussia to challenge the insolence of the Poles, and totally defeated a body of 12,000 men under the command of Czarneski. This did not hinder all the Poles incorporated with his troops to desert; which considerably reduced his army; and the campaign being performed in the depth of winter, he was at last obliged to retreat to Prussia. In his march he was harassed by the Poles; and a body of 4000 Swedes was surprised and defeated by them at Warka. This loss, however, was soon after recompensed by a complete victory gained by Adolphus the king's brother and General Wrangel over Czarneski. In the mean time the king was taking measures for laying siege to Dantzic; but was prevented by the Dutch, who threatened to oppose him, unless a proper regard was paid to their interest. Charles accordingly granted them advantageous terms; and afterwards gained over the elector of Brandenburg, by ceding to him the fove-

reignty of Prussia, that he might be at liberty to turn his whole strength against Poland.

Sweden.

By the treaty just concluded with the elector, the latter was to assist Charles in his war with Poland; but the elector had so procrustean matters, that the Poles, having obtained assistance from the Tartars, had reduced the city of Warfaw. The two princes, however, now marched in concert against their enemies, who were encamped in a strong situation in the neighbourhood of the city abovementioned, their camp being fronted by the Vistula. The Poles were driven from their entrenchments with prodigious slaughter, and a vast number taken prisoners. The Poles and Tartars then laboured to break the alliance; with which view they entered Ducal Prussia, and defeated the electoral army, taking prince Radzivil and other persons of distinction prisoners. The Swedes soon had their revenge. General Steinboeck attacked the same Polish army at Philippowa, and overthrew it with such slaughter as obliged the Poles for that season to quit the field. A more formidable enemy than the Poles now began to make their appearance. The Russians invaded the provinces of Carelia, Ingermania, and Livonia; while the elector of Brandenburg began to waver in his fidelity. To preserve this only ally at such a critical juncture, Charles was obliged to give him more advantageous terms than those already mentioned; while the Russians were repelled in the provinces of Carelia and Ingermania. But in Livonia they had better success, two important fortresses falling into their hands; after which they laid siege to Riga. For seven months they battered the walls of this city, without once venturing to pass the ditch or storm the practicable breaches. The besieged, under the command of Magnus de la Gardie and Simon Helmsfeld, defended themselves with the greatest intrepidity; cutting off many thousands of the enemy in the sallies they made. At last they attacked the Russian camp, drove them out of it with great slaughter, and obliged them to raise the siege with precipitation.

Charles, notwithstanding the number of his enemies, was now become so formidable by the valour and discipline of his troops, that whole armies often fled on the very news of his approach. At last, in 1657, the Poles, finding they could not resist him in the field, contented themselves with harassing the Swedes on their march, and cutting off the foragers and convoys. This proved much more destructive to the Swedes than their former method; so that Charles was obliged to enter into an alliance with Ragotzki prince of Transylvania, by assigning him certain provinces in his neighbourhood, in order to furnish himself with irregular troops, who might fight the Poles in their own way. This, however, proved of no real advantage; for the confederates, after spending a whole campaign in Lithuania, were obliged to return without accomplishing more than the reduction of a single fortress; upon which Charles returned with the Swedish army to Prussia.

ture with him. This was instantly complied with, and the Danes invaded Bremen. Charles hastened to oppose this new enemy; which gave such offence to Ragotzki, that he neglected to take the proper measures for his own defence in the absence of the Swedes, and suffered his army to be destroyed by the Poles and Tartars. At the same time the Turks invaded Transylvania, under pretence that Ragotzki, being a vassal of the Grand Signior, had no right to invade Poland without his leave. Ragotzki opposed them in the field; where he was defeated and killed, leaving Charles destitute of the only ally on whom he could have depended.

The king, however, not dismayed by this misfortune, traversed Pomerania and the duchy of Mecklenburg; after which he fell upon Holstein, while general Wrangel with another corps entered the duchy of Bremen. The latter executed his measures with the utmost vigour and intrepidity. In 15 days he retook all the towns which the enemy had reduced; defeated and drove the Danish army out of the country, killing 3000 of their best soldiers. In Holstein the king reduced several fortresses, laid Itzehoe in ashes, defeated a body of Danes, and laid siege to Frederic-Udda, into which the Danes had thrown a strong garrison. The conduct of this siege he left to Wrangel, he himself retiring to Wismar in order to observe the situation of affairs in Poland; but no sooner was he gone than Wrangel attacked the place with such fury, that he became master of it in two hours. In the province of Halland the Swedes were defeated; but the enemy derived no advantage from their victory: at sea the fleets met, and maintained a hot engagement for two days, without any considerable advantage on either side. In Poland matters went on much worse. The house of Austria had now declared for Casimir; a German army entered Poland, and reduced Cracow, though not without great loss to themselves. Czarnecki entered Pomerania, where he butchered the unhappy peasants without mercy; but on the approach of Charles he fled as usual, having gained nothing by his expedition but the character of a cruel barbarian.

The king of Sweden was now surrounded by enemies. The elector of Brandenburg had declared against him; and he had besides to engage the armies of Austria, Poland, Russia, and Denmark, in the field. In this dangerous situation he resolved to attack Denmark, in such a manner as should oblige that power to come to a speedy accommodation. His designs were forwarded by a very early frost, which enabled him to transport his troops without the expence and trouble of shipping. Having passed over on the ice to the island of Funen, he cut in pieces a body of 4000 Danish soldiers and 500 peasants. The whole island was reduced in a few days; after which he passed to Langeland, then to Laaland, after that to Falster, and lastly to Zealand. The Danes were terrified at this unexpected invasion, and were giving themselves up to despair, when Charles offered to conclude a peace upon equitable terms. The king of Denmark very gladly consented; but with a design to renew the war as soon as he thought it could be done with safety. By this treaty, called the *treaty of Roschild*, concluded on the 22th of March 1658, the provinces of Schonen, Hal-

land, and Bleking; Lyfter, and Huwen, the isle of Borkholm, the baillages of Balus and Drontheim in Norway, were yielded to Sweden, and a free passage through the Sound was granted to the Swedish ships.

No sooner was Charles retired, than the king of Denmark began to act against him in an underhand manner; on which, resolving to anticipate him in his designs, he appeared unexpectedly with a fleet before Copenhagen. Had he given the assault immediately, before the inhabitants had time to recover from their surprize, it would probably have surrendered at once; but, by landing at the distance of 17 miles, he gave them time to prepare for their defence: the siege proved extremely tedious, and at last the place was relieved by a Dutch fleet. On this Charles converted the siege into a blockade, which continued till the end of the war. Wrangel reduced the strong fortresses of Cronenburg; and the Swedish forces were so judiciously posted, that all Denmark was in a manner blocked up; when, in 1660, king Charles died of an epidemical fever; and thus an end was put, for that time, to all the staves, ambitious designs of Sweden.

The new king Charles XI. was a minor at the time of his father's death; and as the kingdom was involved in a dangerous war with so many enemies, the regency determined to conclude a peace, if it could be obtained on reasonable terms. A treaty was accordingly concluded at Oliva; by which Casimir renounced his pretensions to the crown of Poland, and that republic gave up all pretensions to Livonia. Bornholm and Drontheim were ceded to Denmark; and an equivalent in Schonen remained with Sweden. During the minority of the king, nothing remarkable occurs in the history of Sweden. In 1672 he entered into an alliance with Lewis XIV. which, two years after, involved him in a war with the elector of Brandenburg. At first the Swedes carried all before them; but general Wrangel having fallen sick, they continued their conquests under another named *Mardenfeldt*. Almost all the towns in Brandenburg were reduced, when the elector arrived with an army to the relief of his distressed subjects. He retook several towns, defeated Mardenfeldt in a general engagement, and soon after forced them to abandon all their conquests. In conjunction with the Danes, he then invaded the Swedish dominions: many places of importance were reduced, and, in 1676, Sweden received a most destructive blow by the defeat of her fleet in an engagement with the combined fleets of Denmark and Holland. Soon after this the king took the government into his own hands, and in some degree restored the fortune of Sweden; but though matters went on in a more prosperous way where the king commanded in person, the same losses and disgrace attended the Swedish arms in every other quarter. In Pomerania, count Konigsmark lost every place of importance excepting Stralsund, Stetin, and Gripswald. In 1678, the Swedish fleet was defeated in two engagements. At Landskrona a most obstinate battle was fought from ten in the morning till six at night; when both parties were obliged, by their fatigue, to retire to their respective camps. At Oldeval in Norway, the Swedes were defeated; and the Danes laid desolate the islands of Oeland, Smaaland, Unno, and Kuno; while the electoral troops and Imperialists reduced count Konigsmark.

Sweden. mark to the utmost distress in the neighbourhood of Stralsund.

In this deplorable situation of affairs count Konigsmark found an opportunity of attacking his enemies to such advantage, that he obtained a complete victory; after which he ravaged the duchy of Mecklenburg. Yet notwithstanding this success, he could not prevent the elector from reducing Stralsund; after which he was obliged to evacuate Pomerania; and, to complete his distress, the fleet which transported the Swedish army from Pomerania was wrecked on the coast of Bornholm; by which accident 2000 persons were drowned, and the remainder plundered and taken prisoners by the Danes, though they had been furnished with passports from king Frederic.

In this unprosperous situation of affairs a peace was concluded at St Germain's between France and her enemies, by which the Swedes and Danes were left to decide their quarrel by themselves. Denmark was by no means a match for Sweden, even in the distressed situation to which she was reduced: for which reason a treaty was instantly concluded, on terms much more favourable to Sweden than could have been expected; and the peace was confirmed by a marriage between Charles and Ulrica Eleonora, daughter to the king of Denmark. From this time the Swedish monarch applied himself to the reformation of the state; and by artfully managing the disputes between the nobility and peasants, he obtained a decree of the states empowering him to alter the constitution as he pleased. Being thus invested with absolute power, he proceeded to take some very extraordinary measures. In 1685 it was projected to liquidate the public debts by raising the nominal value of money, without adding any thing to its intrinsic value. This was put in execution the following year, by which the creditors of the government lost upwards of nine millions of crowns. This, with some other arbitrary steps taken about the same time, disgusted all the nobility, merchants, and crown-creditors. In Livonia they were highly offended; and remonstrances were repeatedly sent by the hands of deputies, who had orders to insist upon their privileges confirmed by many acts of the king's predecessors. The deputies could obtain nothing, so that the diet was refused. On their report the body of nobility resolved to draw up a stronger remonstrance than any of the former, to be presented to the king by captain Patkul one of the deputies, who had already distinguished himself by his boldness and attachment to liberty. His public spirit, however, produced no other effect than to procure his own destruction. An accusation was drawn up against all the remonstrants, but especially Patkul. He was sentenced to lose his right-hand, then to be deprived of his life, honours, and estates; to have the latter confiscated to the crown, and his papers burnt by the hands of the common executioner. The accusation was declared unjust by the university at Leipzig: but notwithstanding this, Patkul was obliged to fly his country, to avoid the execution of his rigorous sentence; which, however, fell upon him with redoubled fury in the subsequent reign, of which an account is given under the article PATKUL.

On the 15th of April 1697, died Charles XI. leaving his crown to his son, the celebrated Charles XII.

at that time a minor. On his accession he found himself under the tuition of his grandmother Eleonora, who had governed the kingdom during the minority of the late king. Though Charles was at that time only 15 years of age, he instantly showed a desire of taking the government into his own hands. His counsellors, count Piper and Axel Sparre, signified his desire to the queen-regent. They were by her referred to the states; and there all were unanimous: so that the queen, finding that opposition would be vain, resigned her power with a good grace; and Charles was invested with absolute authority, in three days after he had expressed his desire of reigning alone. He was scarce seated on the throne, when a powerful combination was formed against him. King Augustus of Poland formed designs on Livonia; the king of Denmark revived the disputes he had with the duke of Holstein, as a prelude to a war with Sweden; and Peter the Great of Moscow began to form designs upon Ingria, formerly a province of Russia. In 1699 the king of Denmark marched an army into Holstein. Charles sent a considerable body of troops to the duke's assistance; but before their arrival the Danes had ravaged the country, taken the castle of Gottorp, and laid close siege to Tonningen. Here the king of Denmark commanded in person; and was assisted by the troops of Saxony, Brandenburg, Wolfenbuttle, and Hesse-Cassel. England and Holland, as guarantees of the last treaty with Denmark, in concert with Sweden, joined Charles against this confederacy, and sent fleets to the Baltic. They proposed a termination of the war upon equitable terms; but these were haughtily refused by the Danish monarch, who despised the youth and inexperience of Charles, and relied too much upon the alliance he had formed with Saxony, Brandenburg, Poland, and Russia. The town of Tonningen, however, resisted all his efforts; and when he ordered the place to be stormed, he had the mortification to see his troop driven headlong from the walls, by a handful of Swedes under general Banier.

In the year 1700, Charles, having entrusted the affairs of the nation with a council chosen out of the senate, set out on the 8th May from his capital, to which he never after afterwards returned. He embarked at Carlscroon, and defeated the fleet of the allies. Having made a descent on the island Zealand, he defeated a body of cavalry that opposed his march, and then proceeded to invest Copenhagen by sea and land. The king of Denmark then saw the necessity there was either of having his capital destroyed, or of doing justice to the duke of Holstein. He chose the latter; and a treaty was concluded in eleven days, upon much the same terms as formerly. Charles, being thus at liberty to turn his arms against the other princes who had conspired his destruction, resolved to lead his army against Augustus king of Poland; but on his way he received intelligence that the czar of Moscow had laid siege to Narva with 100,000 men. On this he immediately embarked at Carlscroon, though it was then the depth of winter, and the Baltic scarce navigable; and soon landed at Pernaw in Livonia with part of his forces, the rest being ordered to Revel. His army did not exceed 20,000 men; but they were the best soldiers in Europe, while the Russians were only an undisciplined

multitude. The czar, however, had thrown every possible obstruction in the way of his antagonist. Thirty thousand men were posted in a defile on the road, to oppose his passage; and this corps was sustained by a body of 20,000 others, posted some leagues nearer Narva. The czar himself had set out to hasten the march of a reinforcement of 40,000 men, with whom he intended to attack the Swedes in flank and rear. But the celerity and valour of the Swedes baffled every endeavour. With 4000 foot and an equal number of horse the king set out, leaving the rest of the army to follow him at their leisure. With these he attacked and defeated the Russian armies one after another, pushing his way to the czar's camp, which he gave immediate orders for attacking. This camp was fortified by lines of circumvallation and contravallation, by redoubts, by 150 pieces of brass cannon placed in front; and was defended by an army of 80,000 men; yet so violent was the attack of the Swedes, that in three hours the entrenchments were carried; the king with 4000 men that composed the wing he commanded in person, pursued a flying army of 50,000 to the river Narva. The bridge broke down by the weight of the fugitives, and the river was instantly covered with their bodies. Great numbers returned in despair to their camp, where they defended themselves for a while; but at last the generals Gallowin and Frederowitz, who commanded them, surrendered. Thirty thousand were killed in the entrenchments and in the pursuit, or drowned in the river; 20,000 surrendered at discretion, and were dismissed unarmed; while the rest were totally dispersed. An hundred and fifty pieces of fine cannon, 28 mortars, 151 pair of colours, 20 standards, and all the baggage of the enemy, were taken. Among the prisoners were the duke de Croy, the prince of Georgia, and seven other generals. Charles behaved with the greatest generosity to the conquered. Being informed that the tradesmen of Narva had refused credit to the officers whom he detained prisoners, he sent 1000 ducats to the duke de Croy, and to every other officer a proportionable sum.

Generosity
of Charles.

Peter was advancing with 40,000 men to surround the Swedes, when he received intelligence of the dreadful defeat at Narva. He was greatly chagrined; but, comforting himself with the hopes that the Swedes would in time teach the Russians to beat them, he returned to his own dominions, where he applied himself with the utmost diligence to the raising of another army. He evacuated all the provinces which he had invaded, and for a time abandoned all his great projects, thus leaving Charles at liberty to prosecute the war against Poland.

152
Treaty be-
tween the
Czar and
king of Po-
land.

As Augustus had expected an attack, he endeavoured to draw the czar into a closer alliance with him. The two monarchs had an interview at Birsén, where it was agreed that Augustus should lend the czar 50,000 German soldiers, to be paid by Moscow; that the czar should send an equal number of his troops to be trained up to the art of war in Poland; and that he should pay the king three millions of rix-dollars in the space of two years. Of this treaty Charles had notice, and by means of his minister count Piper entirely frustrated the scheme.

In 1701, as early as the season permitted, Charles,

having received a reinforcement from Sweden, took the field, and appeared suddenly on the banks of the Duna, along which the Saxon army was posted to receive him. The king of Poland at that time being sick, the army was commanded by Ferdinand duke of Courland, marshal Stenau, and general Paykel, all officers of valour and experience. They had fortified certain islands in the mouth of the river, and taken every other precaution against an attack; the soldiers were hardy, well-disciplined, and nearly equal to the Swedes in number: yet Charles, having passed the river in boats with high tide, to screen the men from the fire of the enemy, attacked them with such fury, that they were entirely defeated, with the loss of 2500 killed on the spot, and 1500 taken prisoners. All the Saxon baggage, 36 pieces of cannon, five pair of colours, and six standards, fell into the hands of the Swedes.

This victory was followed by the surrender of all the towns and fortresses in the duchy of Courland. The king then passed into Lithuania, where every town opened its gates to him. At Birsén, an army of 20,000 Russians retired with the utmost precipitation on the news of his approach. Here Charles, perceiving that the kingdom of Poland was greatly affected to Augustus, began to project the scheme of dethroning him by means of his own subjects. This scheme he executed with more policy than he ever showed on any other occasion. The manner of putting it in execution was concerted between Radziewisch, cardinal primate of Poland, and count Piper. Intrigues and cabals were held at the house of the treacherous ecclesiastic, while he was publishing circular letters to keep the people in their duty to the king. The diet being filled with Swedish partisans, became tumultuous, and broke up in confusion. The affairs of the kingdom then fell into the hands of the senate; but here the Swedish party was as strong as in the diet. It was agreed that they should send an embassy to Charles; that the polipote should mount, and be ready against all events: but the chief regulations respected the king's authority, which it was determined at any rate to retrench. Augustus, resolving rather to receive laws from the victorious Charles than from his own subjects, sent an embassy to him, committing the management of the whole to the countess of Konigsmark, a native of Sweden, and a lady famous for her wit and beauty. But the king refused to see her; on which she returned, chagrined and disappointed, to Warsaw. The ambassadors of the senate instantly obtained an audience; and were assured by Charles, that he took arms against the Saxons in defence of the liberties of the Poles, whom he should always regard as his best friends. Conferences were appointed to be held at Kinsching; but Charles soon after altered his mind, and told the ambassadors he would hold them at Warsaw.

Augustus, in the mean time, finding his scheme of peace frustrated, had recourse to the senate; but met with such a rough answer from them, that he determined once more to apply to Charles. To him therefore he sent his chamberlain; but a passport being forgot, the ambassador was arrested. Charles continued his march to Warsaw, which surrendered on the first summons; but the citadel held out for some days. Augustus, finding at last that no dependence was to be had on the Poles, determined to

trust

Sweden.

Sweden.

trust his fortune wholly to the Saxon army and the nobility of the palatinate of Cracow, who offered to support him to the utmost of their power. The Saxon army was now advanced to the frontiers, and Augustus immediately put himself at the head of it. Being joined by the nobility of Cracow, he found his forces to amount to 30,000 men, all brave and well-disciplined. With these he marched in quest of his enemy; who did not decline the combat, though he had with him only 12,000 men. Tho' the Saxons were strongly posted, having their front covered by a morass, besides being fortified with pallisades and chevaux de frise, they were attacked with irresistible impetuosity, and entirely defeated, with the loss of 4000 killed, 2000 made prisoners, and all their baggage and cannon. This victory was followed by the loss of Cracow: after which Charles set out in pursuit of the flying army, with a design of preventing them from re-embarking; but his horse falling under him, he had the misfortune to break his thigh, by which he was confined six weeks: and thus Augustus obtained some respite. The interval he made the best use of. Having convoked a diet first at Marienburg, and then at Lublin, from them he obtained the following resolutions; that an army of 50,000 men should be raised by the republic for the service of the prince; that six weeks should be allowed the Swedes to determine whether they were for war or peace; and that the same time should be granted to the turbulent and discontented nobles of Poland to make their concessions. To counteract the effects of these resolutions, Charles assembled another diet at Warfaw; and while the two assemblies disputed concerning their rights and privileges, he recovered of his wound, received a strong reinforcement from Pomerania, and utterly defeated and dispersed the remains of the Saxon army.

The ill fortune of Augustus continued still to persecute him. In 1704 he was formally deposed by the diet, and the crown conferred by Charles on Stanislaus Leszcynski palatine of Posenia. Augustus, however, did not yet tamely give up his kingdom. His adherents daily skirmished with the Swedes; and Augustus himself, being reinforced by 9000 Russians, retook Warfaw, and was very near surprising the new king, who lived in perfect security in the city while Charles fought in his cause. Count Horn, with 1500 Swedes, vigorously defended the citadel; but at last, finding it no longer tenable, he was obliged to surrender at discretion. The reduction of Warfaw was among the last advantages gained by Augustus in the course of this war. His troops were now composed of Saxon recruits and undisciplined Poles, who had no attachment to his person, and were ready on all occasions to forsake him. Charles and Stanislaus advanced with the victorious army; the Saxons fled before them, and the towns for several miles round sent their submissions. The Poles and Saxons were under the command of Schullemburg, a most sagacious and experienced general, who used every expedient to check the progress of the Swedes, by seizing on the advantageous posts, sacrificing small parties to the safety of the whole, and to mislead the enemy, &c. However, with all his conduct and caution, he found himself outwitted, and Charles in the neighbourhood of his camp ready to fall upon him, while he thought

him at 50 leagues distance. The Swedish monarch attacked him with a superior army, but entirely composed of horse. Schullemburg had posted his men in such a manner as rendered it impossible to surround them. His first rank being armed with pikes and fuses, presented a kind of rampart of bayonets; the second line flooping over the first who kneeled, fired over their heads, while the third rank, who stood upon their feet, kept up an incessant fire, by which the Swedish horse were exceedingly galled and put in disorder. Charles lost the opportunity of cutting off the whole Saxon army, by omitting to order his men to dismount. This was almost the first time that infantry had been regularly opposed to cavalry, and the superiority of the former was evident. After the engagement had continued about three hours, the Saxons retreated in good order; which no enemy had ever done before in any engagement with Charles. The Swedes pursued their enemies towards the Oder, and forced them to retreat through thick woods, almost impervious even to infantry. The Swedish horse, however, pushed their way, and at last inclosed Schullemburg between a wood and the river, where Charles had no doubt of obliging him to surrender at discretion, or die sword-in-hand, as having neither boats nor bridges; but the genius of Schullemburg supplied every defect. In the night he ordered planks and floats of trees to be fastened together; upon which he carried over his troops, while the Swedes were employed in dislodging 300 men, which he had placed in a windmill, for the purpose of defending his flank and keeping the enemy in play. Charles spoke of this retreat with admiration, and said he had been conquered by Schullemburg.

No material advantage, however, resulted from this to Augustus; who was again obliged to leave Poland, and fortify the capital of his hereditary dominions, which he expected every moment to see invested. In the mean time, however, the Russians having recovered their spirits, fell upon the Swedes in Livonia with the utmost fury. Narva, Dorpat, and several other towns, were taken, and the inhabitants and garisons treated with great barbarity. Soon after, an army of 100,000 Russians entered Poland. Sixty thousand Cossacks under Mazepa entered the country at the same time, and ravaged every thing with the fury of barbarians. Schullemburg, too, perhaps more formidable than either, advanced with 14,000 Saxons and 7000 Russians, disciplined in Germany, and reputed excellent soldiers. Could numbers have determined the event of war, the Swedes must certainly have been at this time overpowered. Instead of this, however, Charles seemed to triumph over his enemies with more ease the more numerous they were. The Russians were defeated so fast, that they were all dispersed before one party had notice of the misfortunes of another. The

Astonishing success of Charles against them. defeating an army of 40,000 men scarcely obstructed the march of the Swedes, while their astonished enemies looked upon these actions as the effects of witchcraft, and imagined that the king of Sweden had dealings with infernal spirits. With these apprehensions they fled beyond the Boristhenes, leaving the unhappy Augustus to his ill fate. Schullemburg, with all his skill and experience, succeeded no better. The Swedish general Renschild engaged and defeated him in half.

half an hour, though the Swedes were vastly inferior in number, and their enemies posted in a most advantageous situation. Nothing could be more complete than this victory. Whole regiments of Saxons threw down their arms, and begged their lives in the most suppliant posture. Six thousand were slain in the field, and 7000 taken prisoners. Thirty-six pieces of cannon, 11,000 muskets, 40 pair of colours and standards, with all the Saxon baggage, fell into the hands of the Swedes: and the consequences were still more important; for now a passage was opened into Saxony, and Augustus seemed to be in as great danger of losing his hereditary dominions as he had been of losing Poland. This extraordinary victory, indeed, is said to have been owing to a panic which seized the troops of Schullemburg; however, it was looked upon with admiration, and thought to equal the renown of Renschild to that of his sovereign. Charles himself was jealous, and could not help exclaiming, "Surely Renschild will not compare himself with me!" But the cruelty of this general sullied his reputation; for, six hours after the engagement, he caused 1000 Russians to be massacred in cold blood, to revenge, as he said, the cruelties they had committed in Poland.

172 Cruelty of the Swedish general.

Soon after this victory, which was gained on the 12th of February 1706, Charles entered Saxony at the head of 24,000 men. The diet at Ratibon declared him an enemy to the empire if he crossed the Oder. But to this declaration no regard was paid. Charles pursued his march; while Augustus was reduced to the condition of a vagrant in Poland, where he possessed not a single town besides Cracow. Into this city he threw himself with a few Saxon, Polish, and Russian regiments, and began to erect some fortifications for its defence; but the approach of the Swedish general Meyerfeldt, and the news of the invasion of Saxony, disconcerted all his measures, and threw him into despair. The Russians indeed were his faithful allies; but he dreaded them almost as much as the Swedes: so that he was reduced to the necessity of writing a letter to Charles with his own hand, begging for peace on whatever terms he thought proper to grant. However, as he was then at the mercy of the Russians, this transaction was concealed with the greatest care. His emissaries were introduced to the Swedish court in the night-time; and being presented to Charles, received the following answer: That king Augustus should for ever renounce the crown of Poland, acknowledge Stanislaus, and promise never to re-ascend the throne, should an opportunity offer; that he should release the princes Sobieski, and all the Swedish prisoners made in the course of the war; surrender Patkul, at that time resident at his court as ambassador for the Czar of Moscow, and stop proceedings against all who had passed from his into the Swedish service. These articles Charles wrote with his own hand, and delivered to count Piper, ordering him to finish them with the Saxon ambassadors.

174 Augustus begs for peace on any terms.

175 Charles's answer.

176 Augustus, in conjunction with the Russians, defeats and takes prisoner a whole Swedish army.

Augustus all this time was obliged to continue a show of war, though he had neither ability nor inclination to carry it on. He was joined by prince Menzikoff with 30,000 Russians; which obliged him, contrary to his inclination, to come to an engagement with Meyerfeldt, who commanded 10,000 men, one half of whom were Swedes. As at this time no di-

sparity of numbers whatever was reckoned an equivalent to the valour of the Swedes, Meyerfeldt did not decline the combat, though the army of the enemy was four times as numerous as his own. With his countrymen he defeated the enemy's first line, and was on the point of defeating the second, when Stanislaus, with the Poles and Lithuanians, gave way. Meyerfeldt then perceived that the battle was lost; but he fought desperately, on purpose to avoid the disgrace of a defeat. At last, however, he was oppressed by numbers, and forced to surrender; suffering the Swedes, for the first time, to be conquered by their enemies. The whole army were taken prisoners excepting major-general Kraflau; who having repeatedly rallied a body of horse formed into a brigade, at last broke through the enemy, and escaped to Poland. Augustus had scarce sung *Te Deum* for this victory, when his plenipotentiary returned from Saxony with the articles of the treaty above-mentioned. The king But is obliged to sign the crown of Poland. hesitated and scrupled, but at last signed them; after which he set out for Saxony, glad at any rate to be freed from such an enemy as the king of Sweden, and Poland, from such allies as the Russians.

Czar Peter was no sooner informed of this extraordinary treaty, and the cruel execution of his plenipotentiary Patkul, than he sent letters to every court in Christendom, complaining of this gross violation of the law of nations. He intreated the emperor, the queen of Britain, and the States-General, to revenge this insult on humanity. He stigmatized the compliance of Augustus with the opprobrious name of the *pussanimity*; exhorted them not to guarantee a treaty so unjust, but to despise the menaces of the Swedish bully. So well, however, was the prowess of the king of Sweden known, that none of the allies thought proper to irritate him, by refusing to guarantee any treaty he thought proper. At first, Peter thought of revenging Patkul's death by massacring the Swedish prisoners at Moscow; but from this he was soon deterred, by remembering that Charles had many more Russian prisoners than he had of Swedes.

Giving over thoughts of revenging himself in this way, therefore, in the year 1707 he entered Poland at the head of 60,000 men. Advancing to Leopold, he made himself master of that city, where he assembled a diet, and solemnly deposed Stanislaus with the same ceremonies which had been used with regard to Augustus. The country was now reduced to the most miserable situation; one party, through fear, adhered to the Swedes; another was gained over, or forced by Peter to take part with him: a violent civil war took place between the two, and great numbers of people were butchered, while cities, towns, and villages, were laid in ashes by the frantic multitude. The appearance of a Swedish army under king Stanislaus and general Lewenhaupt put a stop to these disorders, Peter himself not caring to stand before such enemies. He retired, therefore, into Lithuania, giving as the cause of his retreat, that the country could not supply him with provision and forage necessary for so great an army.

In the mean time Charles had taken up his residence in Saxony, where he gave law to the court of Vienna, and in a manner intimidated all Europe. He declared himself the protector of the Protestant interest in Ger-

Sweden.

Germany, particularly of the Emperor's Protestant subjects in Silesia. He desired, or rather *commanded*, the Emperor to renew and confirm to them all the liberties granted by the treaties of Westphalia, but since that time reclaimed or eluded at the treaty of Ryfwick. The emperor durst not refuse; and upwards of 100 churches were given to the Protestants. On this occasion the Emperor is reported to have said, that "had Charles desired him to become a Lutheran, he did not know whether he could have refused." One would indeed have imagined that Charles had some thoughts of converting, or at least dethroning, the Pope himself; for being incensed at the constant opposition of the court of Rome, whose weakness and intrigues he despised, he one day told the emperor's minister, that "the Swedes had conquered Rome before now, and he might one day demand an inventory of the effects left there by queen Christina." At last, fatiated with the glory of having dethroned one king, set up another, and struck all Europe with terror and admiration, Charles began to evacuate Saxony, in pursuit of his great plan, the dethroning Czar Peter, and conquering the vast empire of Russia. While the army was on full march in the neighbourhood of Dresden, he took the extraordinary resolution of visiting king Augustus with no more than five attendants. Though he had no reason to imagine that Augustus either did or could entertain any friendship for him, he was not uneasy at the consequences of thus putting himself entirely in his power. He got to the palace-door of Augustus before it was known that he had entered the city. General Fleming having seen him at a distance, had only time to run and inform his master. What might be done in the present case immediately occurred to the minister; but Charles entered the elector's chamber in his boots before the latter had time to recover from his surprise. He breakfasted with him in a friendly manner, and then expressed a desire of viewing the fortifications. While he was walking round them, a Livonian, who had formerly been condemned in Sweden, and served in the troops of Saxony, thought he could never have a more favourable opportunity of obtaining pardon. He therefore begged of king Augustus to intercede for him, being fully assured that his majesty could not refuse to slight a request to a prince in whose power he then was. Augustus accordingly made the request; but Charles refused it in such a manner, that he did not think proper to ask it a second time. Having passed some hours in this extraordinary visit, he returned to his army, after having embraced and taken leave of the king he had dethroned.

184
Marches
against the
Russians.

The armies of Sweden, in Saxony, Poland, and Finland, now exceeded 70,000 men; a force more than sufficient to have conquered all the power of Moscow, had they met them on equal terms. Peter, who had his army dispersed in small parties, instantly assembled it on receiving notice of the king of Sweden's march, was making all possible preparations for a vigorous resistance, and was on the point of attacking Stanislaus when the approach of Charles struck his whole army with terror. In the month of January 1708 he passed the Niemen, and entered the south gate of Grodno just as Peter was quitting the place by the north gate. Charles at this time had advanced

Vol. X.

to some distance before the army at the head of 600 horse. The Czar, having intelligence of his situation, sent back a detachment of 2000 men to attack him; but they were utterly defeated; and this disappointment was followed by the total evacuation of Lithuania. The king pursued his flying enemies in the midst of snow and ice, over mountains, rivers, morasses, and through almost every obstacle that could be surmounted by human power. He had foreseen all difficulties, and determined to surmount them all. As he knew that the country could not furnish provision sufficient for the subsistence of his army, he had provided a great quantity of biscuit, on which his men chiefly subsisted till they came to the banks of the Berезина, in view of Borislow. Here the Czar was posted, and Charles designed to bring him to a battle; after which he could penetrate with the greater ease into Russia. Peter, however, did not think proper to come to an action; but retreated towards the Boristhenes, whither he was pursued by Charles as soon as he had refreshed his army. The Russians had destroyed the roads and desolated the country; nevertheless the Swedish army advanced with great celerity, and in their way defeated 20,000 of the enemy, tho' entrenched to the teeth. This victory, considering the circumstances in which it was gained, was one of the most glorious the Swedes had ever obtained. The memory of it is preserved by a medal struck in Sweden, with this inscription, *Sylox, Paludes, Aggeres, Hostes, victi*.

answer.

When the Russians had repassed the Boristhenes, which separates Poland from Moscow, the Czar, finding himself closely pursued by an enemy with whom he was not able to cope, determined at last to propose peace. Proposals were accordingly made; but Charles returned no other answer, than that he would treat at Moscow; which being reported to Peter, he coolly replied, "My brother Charles affects to play Alexander, but he will not find in me a Darius." However, he did not think proper to venture an engagement, but continued his retreat; and Charles pursued so close, that he was daily skirmishing with the rear of the enemy. In these actions the Swedes had generally the advantage, though in the main these victories proved detrimental, by weakening the army in a country where it was impossible to recruit. Near Smolensko, the king, with only six regiments, defeated a body of 10,000 horse and 6000 Cossacks. In this engagement he was exposed to the utmost danger, the enemy having separated him from his troops. With one regiment only, he fought with such fury as dispersed the enemy, and drove them before him, at the time they thought themselves sure of taking him prisoner. Two aids-de-camp that fought near him were killed; his horse was killed, as was also an equerry while he presented another. The enemy had broke through the regiment, and got quite up to the king; who is said to have on this occasion killed twelve men with his own hand without receiving a wound.

188
Another
desperate
engage-
ment.

By the 3d of October 1708, Charles was within 100 leagues of Moscow; but the Czar had made the roads impassable, either by laying them under water, digging deep ditches, or covering them with the wood of whole forests. He had also destroyed the villages on every side, and taken away every possibility of sub-

sisting an army. The season was also far advanced; the intense severe weather was approaching; so that the Swedes were threatened with all the miseries of cold and famine, at the same time that they were exposed to the attacks of an enemy greatly superior in number, who, from their knowledge of the country, had almost constant opportunities of harassing and attacking them by surprise. For these reasons the king resolved to pass through the Ukrain, where Mazeppa, a Polish gentleman, was general and chief of the nation. Mazeppa having been affronted by the Czar, readily entered into a treaty with Charles, whom he promised to assist with 30,000 men, great quantities of provisions and ammunition, and with all his treasures, which were immense. The Swedish army advanced towards the river Dniester, where they had to encounter the greatest difficulties; a forest above 40 leagues in extent, filled with rocks, mountains, and marshes. To complete their misfortunes, they were led 30 leagues out of the right way; all the artillery was sunk in bogs and marshes; the provision of the soldiers, which consisted of biscuit, was exhausted; and the whole army spent and emaciated when they arrived at the Dniester. Here they expected to have met Mazeppa with his reinforcement; but instead of that, they perceived the opposite banks of the river covered with a hostile army, and the passage itself almost impracticable. Charles, however, was still undaunted; he let his soldiers by ropes down the steep banks; they crossed the river either by swimming, or on rafts hastily put together; drove the Russians from their post, and continued their march. Mazeppa soon appeared, having with him about 6000 broken remains of the army he had promised. The Russians had got intelligence of his designs, defeated and dispersed his adherents, laid his towns in ashes, and taken all the provisions collected for the Swedish army. However, he still hoped to be useful by his intelligence in an unknown country; and the Cossacks, out of revenge, crowded daily to the camp with provisions.

Worse misfortunes, however, still awaited the Swedes. When Charles entered the Ukrain, he had sent orders to General Lewenhaupt to meet him with 15,000 men, 6000 of whom were Swedes, and a large convoy of provisions. Against this detachment Peter now bent his whole force, and marched against him with an army of 65,000 men. Lewenhaupt had received intelligence that the Russian army consisted only of 24,000; a force to which he thought 6000 Swedes superior, and therefore disdained to entrench himself. A furious contest ensued; in which the Russians were defeated with the loss of 15,000 men. The Swedes continued their march; but, by the treachery of their guide, were led into a marshy country, where the roads were made impassable by deep ditches and trees laid across. Here he was again attacked by the Czar with his whole army. Lewenhaupt had sent a detachment of two battalions to dispute the passage of the enemy over a morass; but finding they were likely to be overpowered, he marched at the head of the whole infantry to their relief. Another desperate battle ensued; when at last the Russians were put in disorder, and on the point of being totally defeated, when the Czar gave orders to the Cossacks and Calmucks to fire upon all the Russians who fled. "Even

kill me (said he) if I should be so cowardly as to turn my back." On this the battle was renewed with great vigour; but notwithstanding these positive orders, and the example of the Czar himself, the Russians were a third time put in disorder, after losing 6000 men, when general Baver arrived with a strong reinforcement of fresh Russian troops. The engagement was again renewed, and continued without intermission till night. The Swedes took possession of an advantageous post; but were next morning attacked by the Russians. Lewenhaupt had formed a kind of rampart of his wagons, but was obliged to set fire to them, in order to prevent their falling into the hands of the enemy, and at the same time to cover his retreat by the smoke. The Russians, however, came soon enough to have 5000 wagons of those provisions designed for the distressed Swedes. A strong detachment was sent to pursue Lewenhaupt; but so terrible did he appear, that the Russian general offered him an honourable capitulation. This was refused with disdain; and the battle renewed with the same vigour as before. The Swedes, though reduced to 4000, again defeated their enemies, and killed 5000 on the spot. After this, Lewenhaupt was suffered to pursue his march without molestation, but also without cannon or provisions. Prince Menzi-haupt joins koff, indeed, was detached to harass him; but such was the formidable appearance of the Swedes even in their distress, that he was afraid to attack them: so that at last the 4000 arrived safe in the camp of Charles, after having killed upwards of 30,000 of the enemy on their march.

This, we may say, was the last effort of Swedish valour. The difficulties they had now to undergo exceeded what human nature could bear; yet still they hoped, by constancy and courage, to overcome every obstacle. In the severest winter known for a long time even in Russia, they made long marches, clothed like savages in the skins of wild beasts; all the draught-horses perished; thousands of soldiers dropped dead with cold and hunger: so that by the month of February 1709, the whole army was reduced to 18,000 Swedes. Amidst numberless difficulties these penetrated at last to Pultowa, a town on the eastern frontier of the Ukrain, where the Czar had laid up magazines, and of these Charles resolved to get possession. Mazeppa advised the king to invest the place, in consequence of his having correspondence with some of the inhabitants, by whose means he hoped it would be surrendered. However, he was deceived; the besieged made an obstinate defence, the Swedes were repulsed in every assault, and 8000 of them were defeated, and almost entirely cut off, in an engagement with a party of Russians. To complete his misfortunes, Charles received a shot from a carbine in his heel, which shattered the bone. For six hours after he continued calmly on horseback, giving orders, till he fainted with the loss of blood; after which he was carried into his tent. It was imagined that amputation would be necessary, as the wound had already begun to mortify; but one Newman undertook to save the limb. It was told the king that deep incisions would be necessary. "Fall to work then (said he), cut boldly, and fear nothing." He held out his leg while the operation was performing; never changed

100 The Swedes
men, had lain at a small distance, harassing the Swedish camp, and cutting off the convoys of provisions; but now intelligence was received, that he was advancing as if with a design of attacking the lines. In this situation, Charles, wounded, distressed, and almost surrounded by enemies, is said to have, for the first time, assembled a grand council of war; the result of which was, that it was expedient to march out and attack the Russians. Voltaire, however, totally denies that the king relaxed one jot of his wonted obstinacy and arbitrary temper; but that, on the 7th of July, he sent for general Renchild, and told him, without any emotion, to prepare for attacking the enemy next morning.

100 Battle of
Pultowa. The 8th of July 1709 is remarkable for the battle which decided the fate of Sweden. Charles having left 8000 men in the camp to defend the works and repel the sallies of the beleagued, began to march against his enemies by break of day with the rest of the army, consisting of 26,000 men, of whom 18,000 were Cossacks. The Russians were drawn up in two lines behind their intrenchments, the horse in front, and the foot in the rear, with chafms to suffer the horse to fall back in case of necessity. General Slippenbach was dispatched to attack the cavalry; which he did with such impetuosity, that they were broken in an instant. However, they rallied behind the infantry, and returned to the charge with such vigour, that they disordered the Swedes in their turn, and took Slippenbach prisoner. Charles was now carried in his litter to this scene of confusion. The troops were animated by his presence, and returned to the charge; the battle became doubtful, when general Creuk was dispatched by Charles to attack the enemy in flank. Creuk mistook his way, which occasioned the loss of the battle. Peter now dispatched prince Menzikoff with a strong detachment, to post himself between the Swedes and Pultowa, to cut off their communication with their camp, and to fall upon their rear. He executed his orders with great success; cut off a corps de reserve of 3000 men; and thus decided the fortune of the day. The king, however, had ranged his remaining troops in two lines; the foot in the centre, and the horse in the two wings. They had already been twice rallied, and were now attacked with fury on all sides. Charles, in his litter, with his sword drawn in one hand, and a pistol in the other, seemed to be every where present. New misfortunes, however, awaited him. A cannon ball killed both horses in the litter; and scarce were others put in their place, when a second broke the litter itself in pieces, and overturned the king. The soldiers now believing him killed, fell back in consternation. The first line was broke, and the second fled. Charles did every thing in his power to restore order; but the Russians pressed so hard, that rallying was impossible, especially as powder was also wanting. Renchild and several other general officers were taken prisoners; and the king himself must have fallen into the hands of the enemy, had not count Poniatowsky drawn up 500 horse, surrounded the royal person, and with desperate fury broke through ten regiments of the enemy. With these the king arrived

on the banks of the Boristhenes. The Russians forced the Swedish camp, where they found six millions in specie; but could not hinder Lewenhaupt, with 4000 foot and all the remaining cavalry, from retreating to the banks of the Boristhenes. This, however, availed them but little; for being pursued by prince Menzikoff, they were obliged, for want of boats or bridges, to surrender at discretion. Charles fled in all mean calash, attended by a little troop inviolably attached to his person, some on foot, and some on horseback. They were obliged to cross a sandy desert, where neither herb nor tree was to be seen, and where the burning heat and want of water were more intolerable than the extremities of cold they had formerly suffered. The whole had almost perished for want of water, when a spring was fortunately discovered; after which they reached Ozakow, a town in the Turkish dominions, the bashaw of which supplied the king with every necessary. It was some time, however, before boats could be got ready for transporting the whole of the king's attendants; by which accident 500 Swedes and Cossacks fell into the hands of the enemy. This loss affected him more than all his other misfortunes. He shed tears at seeing across the river Bogh the greater part of his few remaining friends carried into captivity, without having it in his power to assist them. The bashaw waited upon him to apologize for the delay, and was severely reprimanded by Charles, as if he had been his own subject.

The king remained but a few days at Ozakow, when the serasquier of Bender sent an aga to compliment him on his arrival in the Turkish dominions, and to invite him to that city. Here he was treated with the utmost hospitality; the Turks practised to its utmost extent their generous maxim of regarding as sacred the persons of unfortunate princes who had taken shelter in their dominions; and perhaps regarded him, notwithstanding his misfortunes, as an ally that might be useful to themselves against the Russians. Every one, indeed, regarded him in his distress. The French king offered him a safe passage from the Levant to Marseilles, from whence he might easily return to his own dominions. But Charles was too obstinate to receive advice. Puffed up with the notion of imitating Alexander the Great, he disdained to return, except at the head of a numerous army; and he yet expected, by means of the Turks, to dethrone his adversary Czar Peter. Negotiations for this purpose, indeed, were carried on in the Turkish divan; and it was proposed to escort Charles with a numerous army to the frontiers of Poland: but the revolution which took place there quickly put an end to all such projects. Augustus thought himself no longer bound to observe the treaty which he had made, than Charles was at hand to force him to it. After the battle of Pultowa, therefore, he entered Poland, and took every measure, in concert with the Czar, for the recovery of his kingdom. Stanislaus was not able to stand before such enemies, but was obliged to leave his dominions and fly to Bender in the disguise of a Swedish officer, in order to share the fortune of Charles.—It was not in Poland alone that the Swedish affairs began to suffer in consequence of the defeat at Pultowa. The Danes quickly invaded the province of Schonen with an army of 13,000 foot and 2500 horse. Only 13,000 Swe-

diff forces remained to defend all the territories possessed by Charles in Germany; and of these only a small part were allotted for the defence of Schonen. The regency of Sweden, however, exerted themselves to the utmost to repel this ungenerous invasion; and having collected an army of 12,000 militia and 8000 regulars, dispatched them under general Steenbock into Schonen. Some Saxon troops were incorporated in this army; and among these a prodigious desertion took place, which the general found it impossible to prevent: and thus the Danes gained several advantages, and at last took Christianstadt. Their insolence on this success was so great, that the Swedes demanded to be instantly led against them. Here the good fortune of Sweden seemed once more to revive. The Danes were driven from a very strong situation, with the loss of 8000 killed and taken prisoners, besides a vast number wounded. The king received the intelligence of this victory with the greatest exultation; and could not help exclaiming, "My brave Swedes, should it please God that I once more join you, we will conquer them all!"

207
But are utterly defeated.

208
The Turks declare war against the Russians.

209
The Czar brought in to a desperate situation, but is relieved by a treaty.

In the mean time Charles, by means of his agents the count Poniatowski and the Sieur Neugebar, used his utmost efforts to procure a rupture between the porte and Russia. For a long time the money bestowed by Peter on the vizirs and janisaries prevailed; but at last, in 1711, the grand signior, influenced by his mother, who was strongly in the interest of Charles, and had been wont to call him *her son*, determined to avenge his quarrel with Peter. He therefore gave orders to the vizir to fall upon the Russians with an army of 200,000 men. The vizir promised obedience; but at the same time professed his ignorance in the art of war, and dislike to the present expedition. The cham of Crim Tartary, who had been gained over by the reputation and presents of the king of Sweden, had orders to take the field with 40,000 of his men, and had the liberty of assembling his army at Bender, that Charles might see that the war was undertaken upon his account. The czar, on this news, left the siege of Riga, where he had continued for some months; and with 24,000 men entered Moldavia, where he was joined by Cantemir a vassal of the porte. The vizir marched against him with a prodigious army, and, through the negligence of the czar, cooped him up in such a manner that he could neither advance nor retreat. In this desperate situation he observed that he was now in as bad a situation as Charles at Pultowa; and gave orders for breaking thro' the enemy with fixed bayonets. The desponding spiritless soldiers, however, were little disposed to execute these orders; when Catharines, wife to the czar, without his knowledge, set on foot a treaty with the vizir; and having soon obtained his consent, had the peace signed in six hours, by which means, in all probability, the whole Russian army was saved.

The new treaty was most violently opposed by count Poniatowski and the cham of Tartary. The former had made the king acquainted with the situation of both armies; on which he instantly set out from Bender, filled with the hopes of fighting the Russians, and taking ample vengeance. Having rode 50 leagues post, he arrived at the camp just as the czar was drawing

off his half-famished troops. He alighted at Poniatowski's tent; and being informed of particulars, instantly flew in a rage to the vizir, whom he loaded with reproaches, and accused of treachery. Recollecting himself, however, he proposed a method by which the fault might be remedied; but finding his proposal rejected, he posted back to Bender, after having by the gross insult showed his contempt of the vizir.

The violent behaviour of Charles did not promote his interest. The vizir perceived that his stay in Turkey might prove fatal to himself; and therefore determined to get him out of the country as soon as possible, either by fair means or foul. Succeeding vizirs adopted the same plan; and at last the grand signior himself wrote a letter to the king, in which he desired him to depart by next winter, promising to supply him with a sufficient guard, with money, and every thing else necessary for his journey. Charles gave an evasive answer, and determined to procrastinate his journey, as well to gratify his own stubborn temper, as because he discovered a correspondence between king Augustus and the cham of Tartary, the object of which, he had reason to believe, was to betray him to the Saxons. When he was therefore again pressed to fix the day of his departure, he replied, that he could not think of going before his debts were paid. Being asked how much was requisite for this purpose, he replied, 1000 purses (A). Twelve hundred purses were instantly sent to the seraskier at Bender, with orders to deliver them to the king of Sweden, but not before he should have begun his journey. By fair promises, however, Charles persuaded him to part with the money; after which, instead of setting out, he squandered away his treasure in presents and gratifications, and then demanded 1000 purses more before he would set out. The seraskier was affronted at this behaviour. He shed tears; and, turning to the king, told him, that his head would be the forfeit of having obliged him with the money. The grand signior, on being acquainted with this shameful behaviour of Charles, flew into a rage, and called an extraordinary divan, where he himself spoke, a thing very unusual for the Turkish monarchs. It was unanimously agreed that such a troublesome guest ought to be removed by force, if he should other means fail. Orders were therefore positively sent to Charles to depart; or, in case of his refusal, to attack him in his quarters. Nothing could equal his obstinacy on this occasion: in spite of the menaces of his enemies, in spite of the intreaties of his friends, he persisted in his resolution; and at last determined to resist with 300 Swedes, being all the attendants he had, an army of 20,000 janisaries well armed and furnished with cannon. At length he was attacked in good earnest; though it must be owned, that even in this extremity the Turks showed their regard to him, and were tender of his life, which the king did not at all return in a similar manner. The most of the Swedes surrendered at once, perhaps as thinking it the only method of saving the king's life. This misconduct, however, had a quite contrary effect. Charles became the more obstinate, the more desperate his affairs seemed to be. With 40 men servants only, and the generals Hord and Dardorff, he determined to defend himself to the last extremity. Seeing his

soldiers lay down their arms, he told the generals, "We must now defend the house. Come, (adds he with a smile), let us fight *pro aris et focis*." The house had been already forced by the Tartars, all but a hall which was near the door, and where his domestics had assembled themselves. Charles forced his way through the janissaries, attended by the generals Hord and Dardorff, joined his people, and then barricaded the door. The moment he entered, the enemy, who were in the house, threw down their booty, and endeavoured to escape at the windows. Charles purged them from room to room with much bloodshed, and cleared the house in a few minutes. He then fired furiously from the windows, killed 200 of the Turks in a quarter of an hour, so that the bashaw who commanded them was at length forced to fet the house on fire. This was done by arrows with lighted matches shot into the roof; but Charles, instead of quitting it, gave orders for extinguishing the fire, in which he himself assisted with great diligence. All efforts, however, were vain: the roof fell in; and Charles, with his few faithful companions, was ready to be buried in the ruins. In this extremity one called out, that there was a necessity for surrendering. "What a strange fellow! (cries the king), who would rather be a prisoner with Turks than mix his ashes with those of his sovereign." Another had the presence of mind to cry out, that the chancery was but 50 paces off, had a stone roof, and was proof against fire. Pleased with the thoughts of again coming to blows, the king exclaimed, "A true Swede! Let us take all the powder and ball we can carry." He then put himself at the head of his troops, and sallied out with such fury that the Turks retreated 50 paces; but falling down in the hurry, they rushed in upon him, and carried him by the legs and arms to the bashaw's tent.

This extraordinary adventure, which favours not a little of infantry, happened on the 12th of February 1713. He was now kept prisoner, with all his retinue; and in this situation he was visited by the unfortunate Stanislaus. The latter, as we have already observed, came in the disguise of a Swedish officer, and had indeed served in the Swedish army in Pomerania, for which reason he was arrested in the Turkish dominions; but being known at Bender, notice was sent to the bashaw who was conducting the king of Sweden to Adrianople. The bashaw communicated the news to baron Fabricius, a favourite of Charles, who immediately imparted it to the king. "Dear Fabricius, (says this inflexible monarch), run and tell him never to make peace with Augustus; we shall soon have a change in our affairs."

Such were the considerations that still occurred to the mind of Charles; however, at last he seemed inclined to submit to his fate, and began seriously to think of returning to his kingdom, now reduced to the most deplorable situation. His habitation was now fixed at Demotica, a small town about six leagues from Adrianople. Here he was allowed provisions for his own table and those of his retinue; but only 25 crowns a-day in money, instead of 500 which he had received at Bender. During his residence here he received a deputation from Hesse-Cassel, soliciting his consent to the marriage of the landgrave with Eleo-

nora princess royal of Sweden; to which he readily agreed: a deputation was also sent him by the regency of Sweden, requesting that he would prepare for returning to his own dominions, which were ready to sink under a ruinous war in his absence. What determined him, however, more than any thing to hasten his return, was the following accident. The new grand vizir Ibrahim Molla, having for private reasons determined to come to a rupture with the czar, invited Charles to a conference, in the style and with the familiarity of an equal. Charles was so much chagrined at this indignity, that he sent his chancellor Mullern to meet the vizir, with a pretence that he was sick. To avoid giving offence to this minister, Charles was obliged to keep his bed during his residence at Demotica, which was for 10 months after. At last, this vizir being strangled, and the Swedish interest at the porte thereby entirely ruined, he determined to quit Turkey at all events. His departure was to be negotiated by his favourite Grothufen, whom he vested with the character of ambassador extraordinary; sending him to Adrianople with a train of 14 persons richly dressed. To equip this retinue the king was reduced to the most mortifying shifts, and to the necessity of borrowing money from usurers at 50 per cent. The great object was, to obtain from the vizir money and a passport. Grothufen was received with all the respect due to his rank; but the vizir started difficulties. With regard to the passport, he said, it could be of no use until the consent of the court of Vienna was first obtained; and as to money, he said, "his master knew how to give when he thought proper, but it was beneath his dignity to lend; that the king should have every necessary provided for his journey, and possibly the porte might make some pecuniary present, but he would not have it expected." The Imperial minister, however, removed every difficulty with regard to the passport, by granting it in the most full and ample manner, in the name of the emperor, the princes and states of Germany. He sent also a present to the king, consisting of a tent of scarlet richly embroidered with gold; a sabre, the handle of which was studded with jewels; and eight fine horses richly caparisoned. Money, the article most wanted, was entirely forgot; however, the day was fixed for Charles's departure, and the vizir appointed 60 carriages loaded with all kinds of provisions, and several companies of janissaries and other troops to attend him to the frontiers of Transylvania.

On the 14th of October 1714, Charles quitted his bed at Demotica, and set out for Sweden. All the princes through whose territories he was to pass, had given orders for his entertainment in the most magnificent manner; but the king perceiving that these compliments only rendered his imprisonment and other misfortunes more conspicuous, suddenly dismissed his Turkish attendants, and, assembling his own people, bid them take no care about him, but make the best of their way to Stralsund. After this he set out post, in the habit of a German officer, attended only by colonel During. Keeping the bye-roads through Hungary, Moravia, Austria, Bavaria, Wirtemberg, the palatinate, Westphalia, and Mecklenburg, arrived on the 21st of November at midnight, before the gates of Stralsund. Being unknown, he was admitted with

difficulty; but being soon recognized by the governor, the greatest tokens of joy were shown all over the town. In the midst of the tumult Charles went to bed. He had been booted for 16 days, and now his legs were swelled to such a degree that his boots were cut off. Having slept for some hours, he arose, reviewed his troops, and gave orders for renewing the war with redoubled vigour.

225
Distressed
situation of
Sweden.

Sweden was now in the greatest distress. We have already mentioned, that on the news of the defeat at Pultowa, the Danes had invaded Schonen, but were defeated by general Steenbock. This victory, however, did not put an end to the war. On the contrary, the kings of Denmark and Poland, with the czar of Moscow, entered into stricter bonds of amity than ever. They dreaded the return of Charles to his own dominions, and apprehended that numberless victories would soon efface the remembrance of Pultowa. They determined, therefore, to make the best use of their time; and perhaps Charles never took a more imprudent resolution than obstinately to remain so long in the Turkish dominions. The kings of Denmark and Poland invaded Pomerania; but after laying siege in vain to Stralsund, Wismar, and other places, they were obliged to retire with disgrace into winter-quarters. In 1712, the king of Denmark invaded and reduced Bremen and Verden; but the same year met with a terrible defeat from Steenbock, with the loss of a vast number killed and wounded, and almost all their artillery taken. The following year, however, this general being pursued, and surrounded by the united forces of the Russians, Danes, and Saxons, was obliged to throw himself into the neutral town of Tommingen; where he was besieged, and obliged to surrender at discretion, with his whole army. The consequence of this disaster was an invasion of Finland by the czar; which province he totally reduced, after defeating the Swedes in several engagements. Indeed, the Swedish forces were now so much reduced, that they were unable to cope with almost any enemy. The return of Charles, however, seemed to give new life to the whole nation. Though the number of inhabitants was visibly diminished, the levies he had ordered were complete in a few weeks: but the hands left to cultivate the earth consisted of the infirm, aged, and decrepid; so that a famine was threatened in consequence of the military rage which had seized all the youth of the kingdom.

217
The king is
unable to
retrieve the
Swedish af-
fairs.

The preference of Charles did not now produce those consequences which the allies had feared. The kingdom was too much reduced to be able to furnish the necessary supplies of men and money; and though the king's courage and military skill were not in the least diminished, the efforts he made, instead of restoring Sweden to its splendour, served entirely to ruin it. In 1715, Prussia declared against him, on account of his demanding back the town of Stetin, which that monarch had seized. To complete his embarrassment, the elector of Hanover, George I. of Britain, also became his enemy. The forces of Denmark, Prussia, Saxony, and Hanover, joined to invest Wismar, while a body of 36,000 men formed the siege of Stralsund; at the same time that the czar, with a fleet of 20 large ships of war, and 150 transports, carrying 30,000 men, threw every part of the Swedish coast into the

greatest consternation. The heroism of Charles could not prevail against so many enemies. So dreadful, however, he still was, that the prince of Anhalt, with 12,000 brave troops, did not think himself a match for this furious enemy when at the head of only 2000, till he had entrenched his army behind a ditch, defended by chevaux de frize. It appeared, indeed, that his precaution was not unnecessary; for, in the night, Charles with his men clambered up the ditch, and attacked the enemy in his usual manner. Numbers, however, at last prevailed; and Charles was obliged to retire, after having seen his favourite Grothufen, general Dardorff and During, the companions of his exile, killed by his side, and himself being wounded in the breast.

This rash attempt was made in order to save Rugen, from whence the town of Stralsund was supplied with provisions. The place was well fortified, and garrisoned with 9000 men, with Charles himself at their head; but nothing could resist the efforts of the enemy. The houses were laid in ashes by the bombs; the walls miserably shattered, and large breaches made in them by the cannon; so that by the 17th of December it was proposed to give the assault. The attack on the horn-work was desperate: the enemy were twice repulsed; but at last, by dint of numbers, effected a lodgment. The next day Charles headed a rally in which he dealt terrible destruction among the besiegers, but was at length overpowered and obliged to retreat into the town. At last his officers, apprehending that he must either fall into the hands of the enemy, or be buried in the ruins of the place, intreated him to retire. A retreat, however, was now almost as dangerous as to remain in the town, on account of the fleets of the enemy with which the sea was covered, and it is thought that this very circumstance induced the king to consent to it. Setting out therefore in a small boat with sails and oars, he passed all the enemy's ships and batteries, and arrived safe at Ystet in Schonen.

To revenge himself for these losses, Charles invaded Norway with an army of 25,000 men. The Danes were every where defeated and pursued with that vigour for which the king of Sweden was so remarkable; but strong reinforcements arriving from Denmark, and provision failing, he was at last obliged to retire, and evacuate the country. Soon after this the Swedes left Wismar; but when every thing seemed to go to wreck, Baron Goertz the chief minister and favourite of Charles found means to set on foot a treaty with the czar of Moscow, by which the most formidable of all Charles's enemies was taken off. The minister found means to work upon the inflexible and stubborn temper of Charles by representing to him that the cessions of certain provinces to Peter would induce him to assist him in his projects of again dethroning Augustus, and of replacing James on the throne of Britain; which last scheme he had projected out of revenge for the elector of Hanover having seized on the duchies of Bremen and Verden. In consequence of the conferences between the czar and Goertz, the former engaged to send into Poland an army of 80,000 men, in order to dethrone that prince whom he had so long long defended. He engaged also to furnish ships for transporting 30,000 Swedes to Ger-

²³⁴ Charles invades Norway again, and lays siege to Frederick's hall, The king had resolved on the conquest of Norway before he dethroned Augustus; and as no difficulties ever deterred him, he marched his army into that cold and barren country in the month of October, when the ground was covered with frost and snow. With 18,000 men he formed the siege of Frederick's hall, though the severity of the frost rendered it almost impossible to break ground. Charles, however, resolved to form trenches; and his soldiers cheerfully obeyed, digging into the ground with the same labour as if they had been piercing a rock. On the 11th of December the king visited the trenches in the midst of a terrible fire from the enemy, imagining that his men might be animated by his presence. He took his post in the most dangerous station he could choose, standing upon a gabion and leaning with his arm over the parapet, while the enemy were firing chain-shot at the very spot where he stood. He was intended to change his station; but he remained obstinate, as if he had been proof against cannon-bullets. At last he was seen to fall on the parapet with a deep groan. A small cannon-ball had struck him on the temple, beat in the left eye, and forced the right quite out of its socket; his right hand in the mean time grasped the hilt of his sword, as if he had meant to revenge the blow.

²³⁵ His extreme rashness, in consequence of which he is killed. Charles XII. was succeeded by his sister the princess Ulrica Eleonora, wife to the hereditary prince of Hesse. On this occasion the states took care to make a previous stipulation for the recovery of their liberties, and obliged the princess to sign a paper to this purpose before entering on the government. Their first care was to make a peace with Great Britain, which the late king intended to have invaded. The Swedes then, to prevent their farther losses by the progress of the Russian, the Danish, the Saxon, and other arms, made many great sacrifices to obtain peace from those powers. The French, however, about the year 1738, formed a dangerous party in the kingdom, under the name of the *Hats*; which not only broke the internal quiet of the kingdom, but led it into a ruinous war with Russia, by which the province of Finland was lost. Their Swedish majesties having no children, it was necessary to settle the succession; especially as the duke of Holstein was descended from the queen's eldest sister, and was, at the same time, the presumptive heir to the empire of Russia. Four competitors appeared; the duke of Holstein Gottorp, prince Frederic of Hesse-Cassel nephew to the king, the prince of Denmark, and the duke of Deux-Ponts. The duke of Holstein would have carried the election, had he not embraced the Greek religion, that he might mount the throne of Russia. The czarina interposed, and offered to restore all the conquests she had made from Sweden, excepting a small district in Finland, if the Swedes would receive the duke of Holstein's uncle, Adolphus Frederic bishop of Lubeck, as their hereditary prince and successor to their crown. This was agreed to; and a peace was concluded at Abo, under the mediation of his Britannic majesty. This peace was so firmly adhered to by the

czarina, that his Danish majesty thought proper to drop all resentment for the indignity done his son. The prince-succesor married the princess Ulrica, third sister to the king of Prussia; and in 1751 entered into the possession of his new dignity, which proved to him a crown of thorns. Through a strange medley of affairs and views of interest, the French had acquired vast influence in all the deliberations of the Swedish senate, who of late have been little better than pensioners to that crown. The intrigues of the senators forced Adolphus to take part in the late war against Prussia: but as that war was disagreeable not only to the people, but also to the king of Sweden, the nation never made so mean an appearance; and upon Russia's making peace with the king of Prussia, the Swedes likewise made their peace, upon the terms of leaving things as they stood at the beginning of the war. Adolphus died dispirited in 1771, after a turbulent reign of twenty years; and was succeeded by his son Gustavus, the present monarch. The most remarkable transaction of this reign is the revolution which took place in the government in the year 1772, by which the king, from being the most limited became one of the most despotic monarchs in Europe. Ever since the death of Charles XII. the whole power of the kingdom had been lodged in the states; and this power they had on all occasions most grievously abused. Gustavus therefore determined either to seize on that power of which they made such a bad use, or which he perished in the attempt. The revolution was effected in the following manner. On the morning of the 19th of August 1772, a considerable number of officers, as well as other persons known to be attached to the royal cause, had been summoned to attend his majesty. Before then he was on horseback, and visited the regiment of artillery. As he passed through the streets he was more than usually courteous to all he met, bowing familiarly to the lowest of the people. On the king's return to his palace, the detachment which was to mount guard that day being drawn up together with that which was to be relieved, his majesty retired with the officers into the guard-room. He then addressed them with all that eloquence of which he is said to be a perfect master; and after insinuating to them that his life was in danger, he exposed to them in the strongest colours the wretched state of the kingdom, the shackles in which it was held by means of foreign gold, and the dissensions and troubles arising from the same cause which had distracted the diet during the course of fourteen months. He assured them that his only design was to put an end to these disorders; to banish corruption, restore true liberty, and revive the ancient lustre of the Swedish name, which had been long tarnished by a venality as notorious as it was disgraceful. Then assuring them in the strongest terms that he disclaimed for ever all absolute power, or what the Swedes call *sovereignty*, he concluded with these words: "I am obliged to defend my own liberty and that of the kingdom, against the aristocracy which reigns. Will you be faithful to me, as your forefathers were to Gustavus Vasa and Gustavus Adolphus? I will then risk my life for your welfare and that of my country."

The officers, most of them young men, of whose attachment the king had been long secure, who did not

Sweden. not thoroughly perhaps see into the nature of the request his majesty made them, and were allowed no time to reflect upon it, immediately consented to every thing, and took an oath of fidelity to him.

230
Resolution
of a Swedish
officer.

Three only refused. One of these, Frederic Cederstrom, captain of a company of the guards, alledged he had already and very lately taken an oath to be faithful to the states, and consequently could not take that which his majesty then exacted of him. The king, looking at him sternly, answered, "Think of what you are doing." "I do," replied Cederstrom, "and what I think to-day, I shall think to-morrow; and were I capable of breaking the oath by which I am already bound to the states, I should be likewise capable of breaking that your majesty now requests me to take."

The king then ordered Cederstrom to deliver up his sword, and put him in arrest.

His majesty however, apprehensive of the impression which the proper and resolute conduct of Cederstrom might make upon the minds of the other officers, shortly afterwards softened his tone of voice; and again addressing himself to Cederstrom, told him, that as a proof of the opinion he entertained of him, and the confidence he placed in him, he would return him his sword without insisting upon his taking the oath, and would only desire his attendance that day. Cederstrom continued firm; he answered, that his majesty could place no confidence in him that day, and that he begged to be excused from the service.

While the king was shut up with the officers, Senator Ralling, to whom the command of the troops in the town had been given two days before, came to the door of the guard-room, and was told that he could not be admitted. The senator insisted upon being present at the distribution of the orders, and sent in to the king to desire it; but was answered, he must go to the senate, where his majesty would speak to him.

The officers then received their orders from the king; the first of which was, that the two regiments of guards and of artillery should be immediately assembled, and that a detachment of 36 grenadiers should be posted at the door of the council-chamber to prevent any of the senators from coming out.

But before the orders could be carried into execution, it was necessary that the king should address himself to the soldiers; men wholly unacquainted with his designs, and accustomed to pay obedience only to the orders of the senate, whom they had been taught to hold in the highest reverence.

240
The king
gains over
the soldiers.

As his majesty, followed by the officers, was advancing from the guard-room to the parade for this purpose, some of them more cautious, or perhaps more timid than the rest, became, on a short reflection, apprehensive of the consequences of the measure in which they were engaged: they began to express their fears to the king, that unless some persons of greater weight and influence than themselves were to take a part in the same cause, he could hardly hope to succeed in his enterprise. The king stopped a while, and appeared to hesitate. A sergeant of the guards overheard their discourse, and cried aloud—"It shall succeed—Long live Gustavus!" His majesty immediately said, "Then I will venture;"—and

stepping forward to the soldiers, he addressed them in terms nearly similar to those he had made use of to the officers, and with the same success. They answered him with loud acclamations: one voice only said, No; but it was not attended to.

In the mean time some of the king's emissaries had spread a report about the town that the king was arrested. This drew the populace to the palace in great numbers, where they arrived as his majesty had concluded his harangue to the guards. They testified by reiterated shouts their joy at seeing him safe; a joy which promised the happiest conclusion to the business of the day.

The senators were now immediately secured. They had from the window of the council-chamber beheld what was going forward on the parade before the palace; and, at a loss to know the meaning of the shouts they heard, were coming down to inquire into the cause of them, when 30 grenadiers, with their bayonets fixed, informed them it was his majesty's pleasure they should continue where they were. They began to talk in a high tone, but were answered only by having the door shut and locked upon them.

The moment the secret committee heard that the senate was arrested, they separated of themselves, each individual providing for his own safety. The king then mounting his horse, followed by his officers with their swords drawn, a large body of soldiers, and numbers of the populace, went to the other quarters of the town where the soldiers he had ordered to be assembled were posted. He found them all equally willing to support his cause, and to take an oath of fidelity to him. As he passed through the streets, he declared to the people, that he only meant to defend them, and save his country; and that if they would not confide in him, he would lay down his sceptre, and surrender up his kingdom. So much was the king beloved, that the people (some of whom even fell down upon their knees) with tears in their eyes implored his majesty not to abandon them.

The king proceeded in his course, and in less than an hour made himself master of all the military force in Stockholm.

The kingdom of Sweden, in its present state, is divided into the following provinces: 1. Sweden Proper. 2. Gothland. 3. Finland. Swedish Lapland. And, 5. The Swedish islands. Great abatements must be made for the lakes, and unimproved parts of Sweden; which are so extensive, that the habitable part is confined to narrow bounds.

The face of Sweden is pretty similar to those of its neighbouring countries; only it has the advantage of soil, &c. navigable rivers.

The same may be said with regard to its climate, soil, &c. Summer bursts from winter; and vegetation is more speedy than in southern climates. Stoves and warm furs mitigate the cold of winter, which is so intense, that the noses and extremities of the inhabitants are sometimes mortified. The Swedes, since the days of Charles XII. have been at incredible pains to correct the native barrenness of that country, by erecting colleges of agriculture, and in some places with great success. The soil is much the same with that of Denmark and some parts of Norway, generally very bad, but in some valleys surprisingly fertile.

Sweden.

The Swedes, till of late years, had not industry sufficient to remedy the one, nor improve the other. The peasants now follow the agriculture of France and England; and some late accounts say, that they rear almost as much grain as maintains the natives. Gothland produces wheat, rye, barley, oats, pease, and beans; and in case of deficiency, the people are supplied from Livonia and the Baltic provinces. In summer, the fields are verdant, and covered with flowers; and produce strawberries, raspberries, currants, and other small fruits. The common people know, as yet, little of the cultivation of apricots, peaches, nectarines, pine-apples, and the like high-flavoured fruits; but melons are brought to great perfection in dry seasons.

Sweden produces crystals, amethysts, topazes, porphyry, lapis-lazuli, agate, cornelian, marble, and other fossils. The chief wealth of the country, however, arises from her mines of silver, copper, lead, and iron. The last-mentioned metal employs no fewer than 450 forges, hammering-mills, and smelting-houses. A kind of a gold mine has likewise been discovered in Sweden; but so inconsiderable, that from the year 1741 to 1747, it produced only 2398 gold ducats, each valued at 9s. 4d. sterling. The first gallery of one silver mine is 100 fathoms below the surface of the earth; the roof is supported by prodigious oaken beams; and from thence the miners descend about 40 fathoms to the lowest vein. This mine is said to produce 20,000 crowns a year. The product of the copper mines is uncertain; but the whole is loaded with vast taxes and reductions to the government, which has no other resources for the exigencies of state. Those subterranean mansions are astonishingly spacious, and at the same time commodious for their inhabitants, so that they seem to form a hidden world. The water-falls in Sweden afford excellent conveniency for turning mills for forges; and for some years the exports of iron from Sweden brought in 300,000 l. sterling. Dr Busching thinks that they constituted two-thirds of the national revenue. It must, however, be observed, that the exportations of the Swedish government, and the importation of American bar-iron into Europe, and some other causes, have greatly diminished this manufacture in Sweden; so that the Swedes very soon must apply themselves to other branches of trade and improvements, especially in agriculture.

243
animal.

The animals differ little from those of Norway and Denmark, only the Swedish horse are known to be more servicable in war than the German. The fishes found in the rivers and lakes of Sweden, are the same with those in other northern countries, and taken in such quantities, that their pikes (particularly) are salted and pickled for exportation. The train-oil of the seals, taken in the gulph of Finland, is a considerable article of exportation.

There is a great diversity of characters among the people of Sweden; and what is peculiarly remarkable among them, they have been known to have different characters in different ages. At present, their peasants seem to be a heavy plodding race of men, strong and hardy; but without any other ambition than that of subsisting themselves and their families as well as

Sweden.

they can: they are honest, simple, and hospitable; and the mercantile classes are much the of the same cast; but great application and perseverance is discovered among them all. One could form no idea that the modern Swedes are the descendants of those who, under Gustavus Adolphus and Charles XII. carried terror in their names through the most distant countries, and shook the foundations of the greatest empires: The principal nobility and gentry of Sweden are naturally brave, polite, and hospitable; they have high and warm notions of honour, and are jealous of their national interests. The drefs of the common people is almost the same with that of Denmark: the better fort are infatuated with French modes and fashion. The common diversions of the Swedes, are skating, running races in sledges, and sailing in yachts upon the ice. They are not fond of marrying their daughters when young, as they have little to spare in their own life time. The women go to plough, thresh out the corn, row upon the water, serve the bricklayers, carry burdens, and do all the common drudgeries in husbandry.

245
Religion.

Christianity was introduced here in the 9th century. Their religion is Lutheran, which was propagated among them by Gustavus Vasa, about the year 1523, as we have already related. The Swedes are surprisingly uniform and unremitting in religious matters; and have such an aversion to Popery, that caltation is the fate of every Roman-catholic priest discovered in their country. The archbishop of Upfal has a revenue of about 400 l. a-year; and has under him thirteen suffragans, besides superintendants, with moderate stipends. No clergyman has the least direction in the affairs of state; but their morals, and the sanctity of of their lives, endear them so much to the people, that the government would repent making them its enemies. Their churches are neat, and often ornamented. A body of ecclesiastical laws and canons direct their religious œconomy. A conversion to Popery, or a long continuance under excommunication, which cannot pass without the king's permission, is punished by imprisonment and exile.

246
Language.

The Swedish language is a dialect of the Teutonic, and resembles that of Denmark. The Swedish nobility and gentry are, in general, more conversant in polite literature than those of many other more flourishing states. They have of late exhibited some noble specimens of their munificence for the improvement of literature and science, particularly natural history.

247

The Swedish commonalty subsists by agriculture, manufacturing, grazing, hunting, and fishing. Their materials for traffic are the bulky and useful commodities of masts, beams, deal-boards, and other sorts of timber for shipping; tar, pitch, bark of trees, pot-ash, wooden utensils, hides, flax, hemp, peltry, furs, copper, lead, iron, cordage, and fish.

Even the manufacturing of iron was introduced into Sweden so late as the 16th century; for till that time they fold their own crude ore to the Hanse-towns, and bought it back again manufactured into utensils. About the middle of the 17th century, by the assistance of the Dutch and Flemings, they set up some manufactures of glass, starch, tin, woollen, silk, soap, leather-

244
character
the
swedes.

Sweden,
Sweep.

leather-dressing, and saw-mills. Bookselling was at that time a trade unknown in Sweden. They have since had sugar-baking, tobacco-plantations, and manufactures of sail-cloth, cotton, fusian, and other stuffs; of linen, alum, brimstone, paper-mills, and gunpowder-mills. Vast quantities of copper, brass, steel, and iron, are now wrought in Sweden. They have also foundries for cannon, forgeries for fire-arms and anchors, armories, wire and flattening-mills, mills also for fulling, and for boring and stamping; and of late they have built many ships for sale.

Certain towns in Sweden, being 24 in number, are called *Staple-towns*, where the merchants are allowed to import and export commodities in their own ships. Those towns which have no foreign commerce, though lying near the sea, are called *land-towns*. A third kind are termed *mine-towns*, as belonging to mine-districts. The Swedes, about the year 1752, had greatly increased their exports, and diminished their imports, most part of which arrive or are sent off in Swedish ships; the Swedes having now a kind of navigation-act, like that of the English. Those promising appearances were, however, blasted, by the madness and jealousies of the Swedish government; and the people so oppressed with taxes, that some important revolution was daily expected in that kingdom.

The revenue of Sweden, since the unfortunate wars of Charles XII. has been greatly reduced. Her gold and silver species, in the late reign, arose chiefly from the king's German dominions. Formerly, the crownlands, poll-money, tithes, mines, and other articles, are said to have produced a million sterling. The payments that are made in copper, which is here the chief medium of commerce, is extremely inconvenient; some of those pieces being as large as tiles; and a cart or wheelbarrow is often required to carry home a moderate sum. The Swedes, however, have gold ducats, and eight-mark pieces of silver, valued each at 5 s. 2 d. and the subsidies paid them by France help to increase their currency.

No country in the world has produced greater heroes or braver troops than the Swedes; and yet they cannot be said to maintain a standing army, as their forces consist of a regulated militia. The cavalry is clothed, armed, and maintained, by a rate raised upon the nobility and gentry, according to their estates; and the infantry by the peasants. Each province is obliged to find its proportion of soldiers, according to the number of farms it contains; every farm of 60 l. or 70 l. per annum, is charged with a foot-soldier, furnishing him with diet, lodging and ordinary cloaths, and about 20 s. a-year in money; or else a little wooden house is built him by the farmer, who allows him hay and pasture for a cow, and ploughs and sows land enough to supply him with bread. When embodied, they are subject to military law, but otherwise to the civil law of the country. It may therefore literally be said, that every Swedish soldier has a property in the country he defends. This national army is thought to amount to above 50,000 men; and Sweden formerly could have fitted out 40 ships of the line; but of late years their ships, together with their docks, are suffered to run to decay.

SWEEP, in the sea-language, is that part of the

mould of a ship where she begins to compass in the rung-heads: also when when the hauser is dragged along the bottom of the sea to recover any thing that is sunk, they call this action *sweeping for it*.

SWEET, in the wine trade, denotes any vegetable juice whether obtained by means of sugar, raisins, or other foreign or domestic fruit, which is added to wines with a design to improve them.

SWEIN-MOTE. See FOREST Courts.

SWIFT (Dr Jonathan), an eminent divine, politician, and wit, was descended from an ancient family; and born at Dublin in 1667, seven months after his father's death. He was educated at Trinity college, Dublin: but minding history and poetry more than academic learning, he was refused his bachelor's degree for insufficiency, though he was at last admitted *speciali gratia*, by favour rather than merit; a circumstance that served as a spur to his future studies. In 1688, being then without support, he was patronized by Sir William Temple, who had married a relation of his mother, by whose means he was introduced to the notice of king William, who offered to make him a captain of horse; but Swift had determined on a clerical life, and after Sir William's death the king took no farther notice of him. He met with several disappointments in his endeavours at preferment, obtaining only two small livings, Lraceror and Rathbigging, in the county of Meath, when he became eminent as a political writer.

While Swift resided at Lraceror, he invited to Ireland a lady, whom he has celebrated by the name of *Stella*. He became acquainted with her while he lived with Sir William Temple. She was the daughter of his steward, whose name was *Johnston*; and Sir William, in consideration of her father's faithful services, left her at his death 1000 l. She was now about eighteen: and was accompanied by Mrs Dingley, a lady who was fifteen years older, and, though related to Sir William, had only an annuity of 27 l. But whatever was Swift's attachment to Mrs Johnston, every precaution was taken to prevent scandal: they never lived in the same house; nor were they ever known to meet but in the presence of a third person. Swift made frequent excursions; but Mrs Johnston was buried in solitude and obscurity; she was personally known only to a few of Swift's most intimate acquaintance, and Mrs Dingley was her only female companion.

In 1701 Swift took his degree of doctor of divinity. He had been educated among the Whigs; and the same year published a Discourse of the contests and dissensions between the nobles and commons of Athens and Rome: this was in behalf of king William and his ministers, against the violent proceedings of the house of commons. But soon after, he attached himself to the Tories; because, as he said, the Whigs had renounced their old principles.

In 1710, being then in England, he was commissioned by the primate of Ireland to solicit the queen to release the clergy from paying the 20th part and first-fruits; and this brought him acquainted with Mr Harley, who, with the rest of the ministers, appears to have cherished him with uncommon assiduity. From this time he supported his new friends with all his power, in pamphlets, poems, and periodical papers;

yet received no gratuity or reward until the year 1713, when he accepted the deanery of St Patrick's, Dublin. A bishopric had been intended for him by the queen; but archbishop Sharp, and a certain great lady, having represented him as a man whose religious sincerity was very doubtful, it was given to another.

It is here proper to observe, that among other persons with whom he became intimately acquainted while in England, was Mrs Vanhomrigh. She was born in Ireland; and had been married to Mr Vanhomrigh, first a merchant of Amsterdam, then of Dublin, where king William gave him very great places; but he dying, left two sons and two daughters; and his sons dying long after, his whole fortune, which was very considerable, fell to the daughters. The widow and the two young ladies came to England in 1709, where they were visited by persons of the first quality; and Swift living near them, used to be much there. During this familiarity, he insensibly became a kind of preceptor to the young ladies, particularly to the eldest, who was then about 20, and was fond of reading, and a great lover of poetry. Hence admiring such a character as that of Swift, she passed from admiration to love, and ventured to make him a proposal of marriage. He at first affected to believe her in jest, then to rally her on so whimsical a choice, and at last gave her an absolute refusal. While he was in this situation he wrote his *Cadenus and Vanessa*; and then returned to the place of his exile, as he usually called it. Soon after Mrs Vanhomrigh died, and left some debts; which it not being convenient for her daughters, who had debts of their own, to pay at present, to avoid an arrest they followed the dean into Ireland.

The first remarkable event of his life after his settlement at the deanery, was his marriage with Mrs Johnson, the daughter of Sir William Temple's steward, the celebrated Stella, after an intimate friendship of more than 16 years; but whatever were the motives to a marriage that was never avowed, the dean and the lady continued to live in the same Platonic manner they had done before. He had hitherto continued to visit Miss Vanhomrigh, but now his visits were less frequent. Soon after, her sister died; and the remains of the family-fortune centering in her, she retired to Selbridge, a small house and estate about 12 miles from Dublin. From thence she frequently wrote to the dean, and pressed him to marry her, but he rallied and still avoided a positive refusal. She pressed him either to accept or refuse her as a wife; upon which he wrote an answer, and delivered it with his own hand, and probably let her into the fatal secret of his being already married: this the unhappy lady did not survive many weeks; however, before her death, she cancelled a will she had made in the dean's favour.

From 1716 to 1720, is a chafm in the dean's life, which it has been found difficult to fill up. Lord Orrery thinks, with great reason, that he employed this time upon *Gulliver's Travels*. The truth is, that Swift's disappointments had rendered him spleenetic; and he frequently indulged himself in an intolerable misanthropy, that, in the midst of all his wit and imagination, is disgusting in several parts of this work.

About the year 1720, the dean distinguished himself

as a patriot, in his *Proposal for the Use of Irish Manufactures*, and by his *Draper's Letters* in opposition to Wood's patent for a copper coinage; which, he clearly showed, was calculated to procure the patentee an exorbitant gain, to the impoverishment of Ireland. These letters rendered him amazingly popular, and from this time the dean's influence in that island was almost without bounds; for he was consulted in whatever related to domestic policy, and particularly to trade.

In 1727, died his wife, the amiable Stella, in the 44th year of her age; a lady possessed of an enchanting beauty, a musical voice, unbounded wit, mingled with sweetness of manners, and a mind adorned with every virtue. She had been declining ever since the year 1724; and it is generally believed that her immature death was occasioned by the peculiarity of the dean's conduct towards her. It is said the dean did at length earnestly desire that she might be publicly owned as his wife; but as her health was then declining, she said it was too late, and insisted that they should continue to live as they had lived before. To this the dean in his turn consented, and suffered her to dispose entirely of her own fortune, by her own name, to a public charity, when she died.

From the death of Stella his life became much retired; the austerity of his temper also increased, and he could not enjoy his public days: these entertainments were therefore discontinued, and he sometimes avoided the company of his most intimate friends; but in time he grew more desirous of company. In 1732, he complains, in a letter to Mr Gay, that "he had a large house, and should hardly find one visitor if he was not able to hire him with a bottle of wine;" and, in another to Mr Pope, "that he was in danger of dying poor and friendless, even his female friends having forsaken him; which," as he says, "vexed him most." These complaints were afterwards repeated in a strain of yet greater sensibility and self-pity: "All my friends have forsaken me.

"Vertiginosus, inops, surdus, male gratus amicis.

"Deaf, giddy, helpless, left alone,

"To all my friends a burden grown."

It is very remarkable, however, that although his mind was greatly depressed, and his principal enjoyment at an end when Mrs Johnson died, yet there is an air of levity and trifling in some of the pieces he wrote afterwards, that is not to be found in any other: such, in particular, are his *Directions to Servants*, and several of his letters to his friend Dr Sheridan.

The fits of giddiness and deafness, to which he had been subjected from a surfeit before he was 20 years old, became more frequent and violent as he grew in years. A presentiment which he had long entertained of that wretchedness which would inevitably overtake him towards the close of life, by the failure of his intellects, clouded his mind with the most melancholy ideas, and tinged every object around him. How far this gloomy sentiment prevailed, we may learn from the following remarkable anecdote mentioned by Mr Faulkner in his letter to lord Chesterfield. "One time, in a journey from Drogheda to Navan, the dean rode before the company, made a sudden stop, dismounted his horse, fell on his knees, lifted up his hands, and prayed in the most devout manner. When

Swift.

Swift.

his friends came up, he desired and insisted on their alighting; which they did, and asked him the meaning. "Gentlemen," said he "pray, join your hearts in fervent prayers with mine, that I may never be like this oak-tree, which is decayed and withered at top, while the other parts are found." In 1736, while he was writing a satire on the Irish parliament, called the *Legion Club*, he was seized with so dreadful a fit of his malady, that he left the poem unfinished; and never after attempted a composition that required a course of thinking. From this time his memory gradually declined; his passions perverted his understanding; and, in 1741, he became utterly incapable of conversation.

The concluding scene of his life was truly affecting, and afforded a striking lesson to check the pride of human genius. Mr Faulkner's account of it is well worth notice: "Swift never was very outrageous; but his memory failed him by degrees for several years together, inasmuch that he forgot all his friends and domesticities. He could not call any of them by their names; nor for cloaths, food, or any necessaries that he wanted. In short, his forgetfulness grew so much upon him, he could not remember any one passage of his life, nor read, nor even tell his letters, for near two years before his death. He likewise lost the use of his speech, excepting now and then uttering some incoherent rambling words, being incapable of asking any questions, or of returning answers; nor could he ask for one necessary of life. During this melancholy situation great care was taken of his person and his food, as he was incapable of dressing, undressing, or helping himself to cloaths or victuals; and so totally was he deprived of all rational faculties, that he was treated like a new-born infant, being taken out of bed, undressed, and put into bed like the youngest child; and had the actions of one, being fond of gold and silver toys, which he would play with or put into his mouth." In this deplorable state of insensibility he lingered until 1745, when the dissolution of his bodily frame followed the extinction of his mental powers. Upon opening the skull, after his death, much water was found in the brain. By his will, which is dated May 1740, he left about 1200*l.* in legacies; and the rest of his fortune, which was about 11,000*l.* to erect and endow an hospital for idiots and lunatics. His works have been often printed, and of various forms.

Swift undoubtedly was a man of native genius. His fancy was inexhaustible. His conceptions were lively and comprehensive; and he had the peculiar felicity of conveying them in language equally correct, free, and perspicuous. His penetration was as quick as intuition; and he was indeed the critic of nature.

As his genius was of the first class, so were some of his virtues.—The following anecdote will illustrate his filial piety. His mother died in 1710, as appears by a memorandum in one of the account-books, which Dr Swift always made up yearly, and on each page entered minutely all his receipts and expences in every month, beginning his year from November 1. He observed the same method all his lifetime till his last illness. At the foot of that page which includes his expences of the month of May 1710, at the glebe-house of Laracor in the county of Meath, where he was then resident, are these remarkable words, which

show at the same time, his filial piety and the religious use which he thought it his duty to make of that melancholy event. "*Memo.* On Wednesday, between seven and eight in the evening, May 10. 1710, I received a letter in my chamber at Laracor (Mr Percival and Jo. Beaumont being by) from Mrs F—, dated May 9. with one inclosed, sent by Mrs Worral at Leicester to Mrs F—, giving an account that my dear mother, Mrs Abigail Swift, died that morning, Monday April 24. 1710, about ten o'clock, after a long sickness: being ill all winter, and lame; and extremely ill about a month or six weeks before her death. I have now lost my barrier between me and death. God grant I may live to be as well prepared for it as I confidently believe her to have been! If the way to heaven be through piety, truth, justice, and clarity, she is there. J. S." He always treated his mother, during her life, with the utmost duty and affection; and she sometimes came to Ireland to visit him after his settlement at Laracor. She lodged at Mr Brent's, the printer, in George's lane, Dublin. She asked Mrs Brent, the landlady, "Whether she could keep a secret?" She replied, "She could very well." Upon which she enjoined her not to make the matter public, which she was now going to communicate to her. "I have a spark in this town, that I carried on a correspondence with whilst I was in England. He will be here presently to pay his address, for he hath heard by this time of my arrival. But I would not have the matter known." Soon after this a rap was heard at the door, and Dr Swift walked up stairs. Mrs Brent retired: but after a little time she was called, and then Mrs Swift introduced her to her son, and said, "This is my spark I was telling you of. This is my lover; and indeed the only one I shall ever admit to pay their addresses to me." The doctor smiled at his mother's humour, and afterwards paid his duty to her every day, unsuspected by Mrs Brent, whom he invited some years afterwards to take care of his family-affairs, when he became dean of St Patrick's: and when Mrs Brent died, he continued her daughter, a poor widow, in the same office.

The liberality of the dean hath been a topic of just encomium with all his admirers: nor could his enemies deny him this praise. In his domestic affairs, he always acted with strict economy. He kept the most regular accounts: and he seems to have done this chiefly with a view to increase his power of being useful. Mr Faulkner informs us, that "his income was 900*l.* per annum, which he endeavoured to divide into three parts, for the following purposes. First, to live upon one-third of it. Secondly, to give another third in pensions and charities, according to the manner in which persons who received them had lived: and the other third he laid by, to build an hospital for the reception of idiots and lunatics." "What is remarkable in this generous man, is this, (says Mr F.) that when he lent money upon bond or mortgage, he would not take the legal interest, but one per cent. below it."

Fires have sometimes happened in Dublin, by which people of all denominations have been sufferers: upon which melancholy occasions the dean always exerted himself, not only in person, by going from house to house to make collections for them, but wrote and recom-

mended.

Swift.

mended their melancholy cafes to the public. He would go to the afflicted sufferers, offer them his service, and would be the first to subscribe in a most princely and generous manner to their relief; which worthy example of his the benevolent citizens of Dublin would imitate.

His charity appears to have been a settled principle of duty, more than an indistinct effort of good-nature: but as it was thus founded and supported, it had extraordinary merit, and seldom failed to exert itself in a manner that contributed most to render it beneficial. He did not lavish his money on the idle and the worthless. He nicely discriminated characters, and was seldom the dupe of imposition. Hence his generosity always turned to a useful account: while it relieved distress, it encouraged industry, and rewarded virtue.

We dwell with great pleasure on this truly excellent and distinguishing part of the dean's character: and for the sake of his charity we can overlook his oddities, and almost forgive his faults. He was a very peculiar man in every respect. Some have said, "What a man he would have been, had he been without those whims and infirmities which shaded both his genius and his character!" But perhaps the peculiarities complained of were inseparable from his genius. The vigour and fertility of the root could not fail now and then of throwing out superfluous suckers. What produced these, produced also the more beautiful branches, and gave the fruit all its richness.

It must be acknowledged, that the dean's fancy hurried him into great absurdities and inconsistencies, for which nothing but his extraordinary talents and noble virtues, discovered in other instances, could have atoned. The rancour he discovered on all occasions towards the dissenters, is totally unjustifiable. No sect could have merited it in the degree in which he always showed it to them; for, in some instances, it bordered on downright perfection. He doubtless had his reasons for exposing their principles to ridicule; and might perhaps have sufficient grounds for some of his accusations against their principal leaders in Ireland: but nothing could justify his virulence against the whole body.

It must likewise be admitted, that when Swift's resentment was excited, it generally arose to indignation. Amidst the constellation of virtues which shed a distinguishing lustre on his character, he wanted one that a minister of Christianity ought to be ambitious of numbering amongst the chief ornaments of his profession, and that was *forgiveness*. This is a virtue that requires a great share of humility; and Swift seemed to consider himself as having a prescriptive right to haughtiness. His pride gave a dignity indeed to some parts of his conduct; but it frequently transgressed all the bounds of common civility and Christian confession. His pride was not gratified with lowering on those he hated with a supercilious brow; it must trample them under his feet. He could not laugh away his resentment. "It stuck to his last sand;" and gained strength by its duration.

Of Dr Sharp the archbishop of York, who hindered his promotion in the church by insinuating something to the prejudice of his religion, he never spoke but with a tone of indignation that marked a settled rancour. Dr Tenison the archbishop of Canterbury, he

calls, for the same good reason, "the most good-for-nothing prelate that ever lived." Mr Nicols, the editor of a late Supplement to Swift's works, hath transcribed, from an authentic MS. in the possession of Thomas Astle, Esq; a sort of a counter-part to *Macky's Characters*, annexed to the *Memoirs of Secret Services*, in which the dean hath discovered his keenness of observation and severity of resentment against some of the most distinguished characters of the court of George I. The following are a few instances.

Lord Wharton (A).—"He is one of the completest gentlemen in England: hath a very clear understanding and manly expression; with abundance of wit." *MACKY*.—"The most universal villain I ever saw." *SWIFT*, MS.

Earl of Galway. "He is one of the finest gentlemen in the army, with a head fitted for the cabinet as well as the camp: is very modest, vigilant, and sincere: a man of honour and honesty: without pride or affectation." *MACKY*.—"In all directly otherwise. A deceitful, hypocritical, seditious knave: a damnable hypocrite: of no religion." *SWIFT*, MS.

Of John duke of Argyle, Swift says in his MS. "Ambitious, covetous, cunning Scot: has no principles but his own interest and greatness: a true Scot in his whole deportment."—Of the earl of Derby: "As arant a scoundrel as his brother."—Of the duke of Grafton: "Almost a slobberer: without one good quality."—Lord Cholmondeley: "Good for nothing, as far as ever I knew."—Lord Guildford: "A mighty silly fellow."—Duke of Marlborough: "Detestably covetous."—Earl of Sandwich: "As much a puppy as ever I saw; very ugly, and a fop."—Speaker of the house of commons: "A heavy man."

The natural acrimony of Swift's temper, as already observed, had been increased by repeated disappointments. This gave a splenetic tincture to his writings; and amidst the duties of private and domestic life, it too frequently appeared to shade the lustre of his more eminent virtues.—The dean hath been accused of avarice, but with the same truth as he hath been accused of infidelity. In detached views, no man was more liable to be mistaken. Even his genius and good sense might be questioned, if we were only to read some passages of his writings. To judge fairly and pronounce justly of him, as a man and as an author, we should examine the uniform tenor of his disposition and conduct, and the general nature and design of his productions. In the latter, he will appear great; and in the former, good; notwithstanding the puns and puerilities of the one, and the absurdities and inconsistencies of the other.

SWIMMING, the art of suspending one's self on water; and at the same time making a progressive motion through it.

As swimming is not natural to man, it is evident, that at some period it must have been unknown among the human race. Nevertheless there are no accounts of its origin to be found in the history of any nation; nor are there any nations so barbarous that the art of swimming is known among them, and that in greater perfection than among civilized people. It is probable, therefore, that the art, though not absolutely natural, will always be acquired by people in a savage

Swift,
Swimming.

state,

Swimming.

Swimming.

state from imitating the brute animals, most of whom swim naturally. Indeed, so much does this appear to be the case, that very expert swimmers have recommended it to those who wished to learn the art, to keep some frogs in a tub of water constantly beside, and to imitate the motions by which they move through that element.

The theory of swimming depends upon one exceeding simple principle; namely, that if a force is applied to any body, it will always move towards that side where there is the least resistance. Thus, if a person standing in a boat pushes with a pole against the side or any other part of the vessel in which he stands, no motion will ensue; for as much as he presses in one direction with the pole, just so much does the action of his feet, on which the pressure of the pole must ultimately rest, push the vessel the other way: but if, instead of the side of the vessel, he pushes the pole against the shore, then only one force acts upon it, namely, that of the feet; which being resisted only by the fluid water, the boat begins to move from the shore. Now the very same thing takes place in swimming, whether the animal be man, quadruped, bird, or fish. If we consider the matter simply, we may suppose an animal in such a situation that it could not possibly swim: thus, if we cut off the fins and tail of a fish, it will indeed float in consequence of being specifically lighter than the water, but cannot make any progressive motion, or at least but very little in consequence of wriggling its body; but if we allow it to keep any of its fins, by striking them against the water in any direction, the body moves the contrary way, just as a boat moves the contrary way to that in which the oars strike the water. It is true, that as the boat is but partly immersed in the water, the resistance is comparatively less than when a frog or even any other quadruped swims; but a boat could certainly be rowed with oars though it was totally immersed in water, only with less velocity than when it is not. When a man swims, he in like manner strikes the water with his hands, arms, and feet; in consequence of which the body moves in a direction contrary to the stroke. Upon this principle, and on this only, a man may either ascend, descend, or move obliquely, in any possible direction in the water. One would think, indeed, that as the strength of a man's arms and legs is but small, he could make but very little way by any stroke he could give the water, considering the fluidity of that element. Nevertheless it is incredible what expert swimmers will perform in this way; of which Mr Forster gives a most remarkable instance in the inhabitants of O-Taheitee; whose agility, he tells us, was such, that when a nail was thrown overboard, they would jump after it into the sea, and never fail to catch it before it came to the bottom.

As to the practice of swimming, there are but few directions which can be given. The great obstacle is the natural dread which people have of being drowned; and this it is impossible to overcome by any thing but accustoming ourselves to go into the water. With regard to the real danger of being drowned, it is but little; and on innumerable occasions arises entirely from the terror above mentioned, as will appear from the following observations by Dr Franklin.

"That though the legs, arms, and head of a human body, being solid parts, are specifically somewhat heavier than fresh water, yet the trunk, particularly the upper part, from its hollowness, is so much lighter than water, as that the whole of the body, taken together, is too light to sink wholly under water, but some part will remain above until the lungs become filled with water; which happens from drawing water into them instead of air, when a person in the fright attempts breathing while the mouth and nostrils are under water.

"2dly, That the legs and arms are specifically lighter than salt-water, and will be supported by it: so that a human body would not sink in salt-water though the lungs were filled as above, but from the greater specific gravity of the head.

"3dly, That therefore a person throwing himself on his back in salt-water, and extending his arms, may easily lie so as to keep his mouth and nostrils free for breathing; and, by a small motion of his hands, may prevent turning, if he should perceive any tendency to it.

"4thly, That in fresh water, if a man throws himself on his back near the surface, he cannot long continue in that situation, but by a proper action of his hands on the water. If he uses no such action, the legs and lower part of the body will gradually sink till he comes into an upright position; in which he will continue suspended, the hollow of the breast keeping the head uppermost.

"5thly, But if in this erect position the head is kept upright above the shoulders, as when we stand on the ground, the immersion will, by the weight of that part of the head that is out of water, reach above the mouth and nostrils, perhaps a little above the eyes; so that a man cannot long remain suspended in water with his head in that position.

"6thly, The body continued suspended as before, and upright, if the head be leaned quite back, so that the face looks upwards, all the back-part of the head being then under water, and its weight consequently in a great measure supported by it, the face will remain above water quite free for breathing, will rise an inch higher every inspiration, and sink as much every expiration, but never so low as that the water may come over the mouth.

"7thly, If, therefore, a person, unacquainted with swimming, and falling accidentally into the water, could have presence of mind sufficient to avoid struggling and plunging, and to let the body take this natural position, he might continue long safe from drowning, till perhaps help would come: for as to the cloaths, their additional weight, while immersed, is very inconsiderable, the water supporting it; though when he comes out of the water, he would find them very heavy indeed."

The method of learning to swim is as follows: The person must walk into water so deep that it will reach to the breast. He is then to lie down gently on the belly, keeping the head and neck perfectly upright, the breast advancing forward, the thorax inflated, and the back bent; then withdrawing the legs from the bottom, and stretching them out, strike the arms forwards in unison with the legs. Swimming on the back is somewhat similar to that on the belly; but

Swimming but with this difference, that although the legs are employed to move the body forwards, the arms are generally unemployed, and the progressive motion is derived from the movement of the legs.—In diving, a person must close his hands together, and, pressing his chin upon his breast, make an exertion to bend with force forwards. While in that position, he must continue to move with rapidity under the surface; and whenever he chooses to return to his former situation, he has nothing to do but bend back his head, and he will immediately return to the surface.

It is very common for novices in the art of swimming to make use of corks or bladders to assist in keeping the body above water. Some have utterly condemned the use of these; however, Dr Franklin allows that they may be of service for supporting the body while one is learning what is called the *stroke*, or that manner of drawing in and striking out the hands and feet that is necessary to produce progressive motion. "But (says he) you will be no swimmer till you can place confidence in the power of the water to support you: I would therefore advise the acquiring that confidence in the first place, especially as I have known several who, by a little of the practice necessary for that purpose, have infensibly acquired the *stroke*, taught as it were by nature.

"The practice I mean is this: Choosing a place where the water deepens gradually, walk coolly into it till it is up to your breast: then turn round your face to the shore, and throw an egg into the water, between you and the shore; it will sink to the bottom, and be easily seen there, if the water is clear. It must lie in the water so deep as that you cannot reach it to take it up but by diving for it. To encourage yourself in order to do this, reflect that your progress will be from deeper to shallower water; and that at any time you may, by bringing your legs under you, and standing on the bottom, raise your head far above the water: then plunge under it with your eyes open, throwing yourself towards the egg, and endeavouring, by the action of your hands and feet against the water, to get forward till within reach of it. In this attempt you will find that the water buoys you up against your inclination; that it is not so easy a thing to sink as you imagined; that you cannot, but by active force, get down to the egg. Thus you feel the power of the water to support you, and learn to confide in that power; while your endeavours to overcome it, and to reach the egg, teach you the manner of acting on the water with your feet and hands; which action is afterwards used in swimming to support your head higher above water, or to go forward through it."

SWINE, in zoology. See SUS.

SWITZ, or SCHITZ, the capital of one of the cantons of Switzerland, to which it gives name, seated on the east side of the lake Lucern, in N. Lat. 47. E. Long. 8. 30.

SWITZERLAND, or SWISSERLAND, a country bounded to the south by Savoy, the Milanese, and the territories of Venice; to the north, by Swabia; to the east, by the country of Tyrol, a part of Austria and Swabia; and to the west by the Sandgau, Burgundy, and the country of Gex; being about 260 miles long and 100 broad.

The Swifts were anciently called *Helvetii*; and being subdued by the Romans, they continued in subjection to that power till the empire declined, when they became a part of the kingdom of Burgundy. After that they fell under the dominion of the Franks, then of the Germans; but being oppressed by the latter, they threw off the yoke, and erected several states and republics, which, at the treaty of Westphalia in 1648, were recognized as free and independent. The cantons of Switz, Uri, and Underwald, having, as early as the year 1308, entered into a confederacy in the canton of Switz, and having also obtained their first victory in 1315 over Leopold archduke of Austria in the same canton, its name was given to the whole confederacy, which it still retains. The other cantons successively acceded to this association, but some of them not until upwards of 100 years after. With respect to the government and constitution of these cantons, some of them are aristocracies and some democracies. In the former, both the legislative and executive power is lodged in the burghers or citizens of the capital of each canton; and of these there are seven, viz. Zurich, Bern, Basil, Friburg, Solothurn, and Schaffhausen. In the others, the legislative power is lodged in the whole body of the people; and every male above sixteen, whether master or servant, has a vote in making laws, and in the choice of magistrates. For what concerns the whole Helvetic body, there are diets ordinary and extraordinary: the former are held annually, and the others upon particular emergencies; and both are summoned by the city of Zurich, which appoints the time and place of their meetings. Besides the general diets, since the Reformation, there have been particular diets of the two religions, at which all public affairs of consequence that regard the two parties are treated separately; for though a sense of their common interest obliges them to study to maintain the league and union, yet it is certain, that the mutual confidence between the cantons is in some measure lost through the zeal of each party for their particular opinions, especially of the Roman Catholics. The annual general diets are held always at Frauenfeld or Baden, principally to regulate the affairs of the common bailiages. Lucern takes the lead of the Roman Catholic cantons, being the most powerful of that denomination; but Zurich, though less powerful than that of Bern, takes the precedence of all the other cantons, both Protestant and Popish. These cantons do not make one commonwealth, but are so many independent states united together by strict alliances for their mutual defence. The extraordinary diets or congresses are held at Aldorf. Each canton usually deputed two envoys both to the ordinary and extraordinary, to which also the abbot and town of St Gall, and the town of Biel, send representatives as allies. To the 13 cantons belong in common 21 bailiages, two towns, and two lordships. The allies or incorporated places, as they are called, are the abbot and town of St Gall, the three Grison leagues, the republic of the Valais, the towns of Muhlhausen and Biel, the principality of Neuenburg or Neuchâtel, Geneva, and the bishop of Basil. Of these the abbot and town of St Gall, and the town of Biel, are regarded as members of the Helvetic body, but the rest only as allies.

As to the air, soil, and produce of Switzerland, that part of the canton of Bern to the east of the lake of Geneva, together with the cantons of Uri, Schwyz, Unterwald, Glaris, Appenzel, and part of the canton of Lucern, consist of stupendous mountains, whose tops are said to be from 9000 to 12000 feet above the level of the sea, consisting of craggy inaccessible rocks, of which some are quite bare, while others are always covered with ice and snow. Among the mountains are many excellent medicinal and other springs, cold and warm baths, water-falls, craggy precipices, deep narrow valleys, and caverns. They yield also a great variety of herbs, thickets, and bushes, in the upper parts; and in the lower rich pastures and woods. The highest are those in the canton of Uri. Many of the valleys are covered with lakes, or watered by brooks and rivers. In some of them are towns, villages, woods, vineyards, and corn-lands. Both on the mountains and in the valleys the air is extremely cold in winter; but in summer it is very pleasant, cool, and refreshing on the former, but excessive hot in the latter. Sometimes it is winter on the north side of a mountain when it is summer on the other; nay, flowers may be gathered sometimes with one hand and snow with the other. Prodigious masses of ice and snow often fall from them in winter, and do a great deal of damage; and most of the streams and rivers take their rise from the thawing of the ice and snow on their sides and tops. From the rising or descending of the clouds, with which they are commonly enveloped, the inhabitants can, for the most part, pretty exactly foretell the changes of the weather; so that they serve them instead of weather-glasses. The other and lower parts of Switzerland are very pleasant and fertile, being diversified with vineyards, corn-fields, meadows, and pasture-grounds. The mountains in these are but mole-hills in comparison of the others: there is neither snow nor ice on them in summer; and they frequently afford not only good pasturage, but arable ground. Many petrifications are found both among these and the others, with a variety of fossils. The sands of the rivers yield gold-dust, particularly those of the Rhine, the Emmet, the Aare, the Reusz, the Adda, and the Goldbach. The metals of this country being generally found to be brittle, the only mines that are worked are a few iron ones. In the lower parts of Switzerland they sow rye, oats, barley, spelt, flax, and hemp. Wines of various sorts are also produced in some of them, with a variety of fruits. Of wood for fuel and other uses, there is generally plenty; in some places, however, they are obliged to burn sheep dung, and in others a kind of heath and small shrubs. In the valleys they cultivate saffron with good success. The Swissers derive their principal subsistence from their flocks and herds of cattle, which in summer graze upon the mountains. Their cheese is much esteemed, especially that of Bern and Griers in the canton of Freyburg. Great numbers of horses also are bred here, and bought up for the French cavalry. Besides the above-mentioned rivers, the Rhone and the Telin have their sources in this country. The lakes are very numerous; but the chief are those of Geneva, Neuchâtel, Biel, Zurich, Thun, Brienz, Constance, and Lucern. Both rivers and lakes abound with fish, and afford a cheap water-

carriage. Switzerland is not so populous as many other countries in Europe; and the Popish cantons less so than the Protestant. The total number of the inhabitants is computed at two millions.

The language generally spoken here is the German, in which also all public affairs are transacted; but in those parts of the country that border on Italy or France, a corrupt French or Italian prevails. The two predominant religions are Calvinism and Popery. Of the former are the cantons of Zurich and Bern, the towns of St Gall, Geneva, Muhlhausen, and Biel, the principality of Neuchâtel, the greater part of Basil, Schaffhausen, the country of the Grisons, the Thurgau, Toggenburg, Glaris, and the Rhine valley; the frontiers of Appenzel, with a small part of Solothurn, and some places in the countries of Baden and Sargans. The rest of the Swiss cantons, allies, and dependents, are Popish. For the education of youth there is an university at Basil, and academies at Zurich, Bern, Lausanne, and Geneva, besides gymnasiums and schools illustres, both in the Popish and Swiss cantons. There are also societies among them for the improvement of the German language and the sciences.

The principal manufactures are snuff and tobacco, linen of several sorts, lace, thread, silk and worsted stockings, neckcloths, cotton stufts, gloves, handkerchiefs, silks of several sorts, gold and silver brocades, a variety of woollen manufactures, hats, paper, leather of all sorts, earthen wares, porcelain, toys, watches, clocks, and other hardware, &c. The trade of Switzerland is greatly promoted by many navigable lakes and rivers. In some of the above manufactures, and in cheese, butter, sheep, horses, black cattle, hides, and skins, the exports are considerable; and as the imports are chiefly grain and salt, with some American and Asiatic goods, there is probably a large balance in their favour. In some parts of Switzerland dress is restrained by sumptuary laws.

The public revenues are in general very inconsiderable, arising chiefly from the usual regalia, appropriated every where to the sovereign, the demesnes, and public granaries, voluntary contributions, the sale of salt, and a land-tax; in the Protestant cantons, from the church-lands also that were seized at the Reformation. Except in Zurich, Bern, Basil, and Schaffhausen, where the people are more industrious, have a greater trade, and are richer than in the others, they defray the ordinary charges, and that is all.

The cantons never keep any standing troops, except for a few garrisons; but their militia is reckoned to be the best regulated of any in Europe. Every male from 16 to 60 is enrolled, and about one-third of them regimented. They must all provide themselves with arms, clothing, and accoutrements, and appear on the stated days for exercise; and the several cantons and districts must be furnished with a sufficient train of artillery, and all the other implements of war. The Swissers of the several cantons are allowed to engage in the service of such foreign princes and states as are in alliance with those cantons, or with whom they have made a previous agreement. Such states, paying an annual subsidy to the respective cantons, are allowed to make levies. Every man enlists voluntarily, and for what number of years they please; at the expiration of which they are at liberty to return home. A

Sword
||
Sydenham.

great many thus always returning from foreign service, Switzerland is never unprovided with able and experienced officers and soldiers. With respect to their character, they are a brave, honest, hospitable, hardy people; very true to their engagements, friendly, and humane. In short, there is not a people in Europe whose national character is better. In their persons they are generally tall, robust, and well made; but their complexions are none of the best, and those that live in the neighbourhood of the mountains are subject to wens. The women are said to be generally handsome and well-shaped, sensible and modest, yet frank, easy, and agreeable in conversation. Few of the peasants are miserably poor; many of them are rich, especially in the Protestant cantons, and that of Bern in particular.

SWORD, an offensive weapon worn at the side, and serving either to cut or stab. Its parts are the handle, guard, and blade; to which may be added the bow, scabbard, pommel, &c.

SWORD of State, which is borne before the king, lords, and governors of counties, cities, or boroughs, &c. For or before the king, it ought to be carried upright; the hilt as low as the bearer's waist, the blade up between his eyes. For or before a duke, the blade must decline from the head, and be carried between the neck and the right shoulder. For or before an earl, the blade is to be carried between the point of the shoulder and the elbow: and for or before a baron, the blade is to be borne in the bend of the arm. This ceremonial form no less denotes the dignity of a governor than the coronet set on his coat of arms.

SWORD-Fish. See **XIPHIAS**.

SWORN BROTHERS, (*fratres jurati*), persons who, by mutual oath, covenanted to share each others fortune. Formerly, in any notable expedition to invade and conquer an enemy's country, it was the custom for the more eminent soldiers to engage themselves by reciprocal oaths to share the rewards of their service. This practice gave occasion to the proverb of *sworn brothers or brethren in iniquity*, because of their dividing plunder and spoil.

SYCAMORE-TREE, in botany. See **ACER**.

SYCOPHANT, an appellation given by the ancient Athenians to those who informed of the exportation of figs contrary to law: and hence it is still used in general for all informers, parasites, flatterers, cheats, &c.

SYDENHAM (Dr Thomas), an excellent English physician, was the son of William Sydenham of Winford Eagle in Dorsetshire, and was born there about the year 1624. He studied at Magdalen-hall, Oxford; but left that university when Oxford was garrisoned for king Charles I. and went to London: where becoming acquainted with Dr Thomas Cox, an eminent physician, that gentleman persuaded him to apply himself to the study of physic; and therefore, after the garrison was delivered up to the parliament, he retired again to Magdalen-hall, entered on the medical line, and in 1648 was created bachelor of physic. Soon after, he was made a fellow of All-Souls college, and continued there several years: when, leaving the university, he settled at Westminster, became doctor of his faculty at Cambridge;

grew famous for his practice; and was the chief physician in London from the year 1660 to 1670; at which period he began to be disabled by the gout. He died in 1689. His works are highly esteemed both at home and abroad. He was famous for his cool regimen in the small-pox; for giving the bark after the paroxysm in agues; and for his use of laudanum. He regulated his practice more by his own observations and inquiries, than by the method either of his predecessors or cotemporaries.

SYLLABLE, in grammar, a part of a word consisting of one or more letters pronounced together.

SYLLABUS, in matters of literature, denotes a table of contents, or an index of the chief heads of a book or discourse.

SYLLOGISM, in logic, an argument or term of reasoning, consisting of three propositions; the two first of which are called *premises*, the last the *conclusion*. See **LOGIC**, n° 61, 63, 84—101; and **ORATORY**, n° 30.

SYMBOL, a sign or representation of something moral, by the figures or properties of natural things. Hence symbols are of various kinds; as hieroglyphics, types, ænigmas, parables, fables, &c.

SYMMACHUS, a citizen and senator of ancient Rome, and consul in the year 391, has left us ten books of epistles; from which, as well as from other things, we collect, that he was a warm opposer of the Christian religion. He was banished from Rome by Valentinian on some account or other, but afterwards recalled and received into favour by Theodosius. Ammianus Marcellinus speaks of him as a man of great learning and modesty. Scippius, Pareus, and other learned men, have written notes upon the epistles of Symmachus: we know of no later edition of them than that of Francfort, 1642, 8vo. Ambrose bishop of Milan wrote against Symmachus, and so did the Christian poet Prudentius.

SYMMETRY, the just proportion of the several parts of any thing, so as to compose a beautiful whole.

SYMMETRY, in painting. See **PAINTING**, n° 7.

SYMPATHETIC, something that acts or is acted upon by sympathy. Thus we say sympathetic diseases, inks, &c.

SYMPATHETIC Inks. See **INK Sympathetic**.

SYMPATHY, an agreement of affections and inclinations, or a conformity of natural qualities, humours, temperaments, which make two persons delighted and pleased with each other.

SYMPATHY also denotes the quality of being affected by the affection of another; and may subsist either between different persons or bodies, or between different parts of the same body. It is either similar or dissimilar: similar, when the affection or action in the sympathiser is similar to the affection or action in the sympathant; and dissimilar, when those are different.—Sympathy, too, is often an imitative faculty, sometimes involuntary, frequently without consciousness: thus we yawn when we see others yawn, and are made to laugh by the laughing of another.

Sympathy, according to Dr Jackson, relates to the operations of the affections of the mind, to the operations of the imagination, and to the affections of the external senses.

Syllable
||
Sympathy.

Sympathy.

1. The passions and affections of the mind produce in the body different sensations and impressions, and, as sympathies of consciousness, determine in general the spirits to those parts which labour most, or are most apt to be affected. Thus fear and anger determine to the heart; lust to the eyes, &c.; joy, pity, wonder, and the like, to the head.

Jackson on
Sympathy,
p. 95.

The passions and affections have been said to impress and act upon the body, in the following manner: "1. Fear causeth paleness, trembling, the standing of the hair upright, starting, and shrieking. 2. Grief and pain causeth sighing, sobbing, groaning, screaming, and roaring; they also cause tears, distorting of the face, grinding of the teeth, and sweating. 3. Joy causeth a cheerfulness and vigour in the eyes, singing, leaping, dancing, and sometimes tears. 4. Anger produces paleness in some, and the going and coming of the colour in others; also trembling in some, swelling, foaming at the mouth, stamping, and bending of the fist. 5. Slight, displeasure, or dislike, causes shaking of the head, frowning, and knitting of the brows. 6. Shame causeth blushing, and casting down of the eyes. 7. Pity causes sometimes tears, and a flexion or cast of the eyes aside. 8. Wonder causeth astonishment, and an immovable posture of the body, casting up of the eyes to heaven, and lifting up of the hands. 9. Laughing, though hardly to be considered as a passion, since it is produced by an affection of the mind, causeth a dilatation of the mouth and lips; a continued expulsion of the breath; with a loud noise, which maketh the interjection of laughing, shaking of the breast and sides, and running of the eyes with water, if it be violent and continued. 10. Lust causes a fragrance in the eyes, and priapism."

The affections of the mind of one person will often work upon the spirits of many. Thus whole companies are sometimes disposed to be sad and melancholy, or merry and jovial, when any one is present much inclined to either of those states of mind; and it has been observed, that old people, who have loved the company of the young, and have been conversant continually with them, have generally lived long. But young people must not conclude from this, that the company and conversation of the grave and old will operate upon their living and sensitive principle, thro' the affections of their mind, and dispose them to be short-lived. On the contrary, by thus improving their understanding, they will be more enabled to fortify their constitution and resist the ravages of youthful indulgence.

It may also be further observed, that those tender sympathetic affections which lay hold of the mind, at the representation of theatrical performances, originate from the same principle, while they are to be considered as the surest test of just execution in the actor, and of the expressive language of the author. Indeed all stage-effect depends on sympathy.

The affections of the mind make the spirits more powerful and active, especially those which manifest themselves by the eyes. Two in particular may be named, *love* and *envy*. As sympathies of consciousness, their operations are more easily felt than described. Though opposite in their nature, they are equally violent in obtaining their particular ends. The one can

no more suffer indifference and disappointment, than Sympathy: the other contempt and haughtiness.

It has been said, that the passions of the mind are occasionally ineffective, particularly some of them. Thus *fear* and *shame* are sometimes very suddenly so. We frequently may have occasion to see, that the starting of one will make another ready to start. Again, when one man is out of countenance in company, others will often blush in his behalf. However, the serious passions may surely be so under the controul of reason as to resist infection, whatever may be the cause of temporary, muscular, or nervous attraction.

2. Our author is inclined to think, that a connection between the affections and sensations of the female mind and uterus is very materially concerned in the process of generation, and probably can alone give efficacy to those actions and impressions subservient to conception, through the sympathizing affections of the mind.

One of the first medical philosophers of the present time, he observes, is of opinion that the mother has always the powers and principles of fashioning her child within herself, but that they are not roused to action without the stimulating influence of the male. The principles that must be immediately concerned are the sensitive and living; but it is through the influence of the mental principle that the form and image of the embryo is stamped.

With respect to the depravity and force of the imagination in the production of sympathies, they always operate most upon "weak minds and spirits, and therefore most on women, superstitious and fearful persons, sick people, children, and young creatures." "Their effects, however, sometimes fail to appear, because they are encountered and overcome by the mind and spirit before they work any manifest effects."

Such effects are obviated upon the same principle which establishes the prevention of bodily disease: "for in infection and contagion from body to body (as, for example, during the plague), the miasma may be received; but from the strength and good disposition of the body, it is expelled and wrought out before it has had sufficient time to form the disease."

It has been said, and many are of the opinion, that the force of imagination doth often forward the end proposed. Thus, for instance, it has been put as a question, "Whether a man, when he constantly and strongly believes that such a thing shall be (as that such a one will love him, and the like), helps any thing to the effecting the thing desired?" Certainly not in the manner which has been advanced, namely, "by a secret operation on the spirit of another." If he succeeds, it is either because he persevered, or because his perseverance and earnestness (and not any occult operation) makes him at length be attended to.

There is not a doubt but the force of imagination often gives energy to our actions. It may, however, unless we are much on our guard, easily delude us aside from reason. It has been the tree which has yielded the fruits of superstition in former times, and which has often fed the human mind with the most extravagant notions of sympathy. Sympathies of this kind, such as the power of charms, and the like, are

now

Sympathy. now pretty generally exploded.

3. The five principal senses, *hearing, tasting, smelling, feeling, and seeing*, are conscious of a sympathetic impression from odious objects. "1. A disagreeable sound will set the teeth on edge, and make all the body shiver. 2. The swallowing of a nauseous medicine will be attended with a shaking of the head and neck. 3. Disagreeable smells produce nearly the same effect, which are less perceived, because there is a remedy at hand by stopping the nose. 4. If you come suddenly out of the sun into the shade, the sense of feeling is disturbed by a chillness or shivering of the whole body. 5. And even sudden darkness produces a propensity to shivering."

2011.

There is a very apparent reason why a sympathy should take place between the eyes. Hence their motions are synchronous. It may be said, that custom and habit dispose the eyes to move one and the same way; "for when one eye moveth towards the nose, the other eye moveth from the nose."

Though the eyes are by nature prone to move in concert, custom will, however, destroy this natural consent, and produce the contrary. Thus some people can squint when they will. Our author therefore gives this caution to mothers and nurses: "Let them not suffer infants to sit with a candle placed behind them; for both their eyes will dispose to move outwards, as affecting to see the light of the candle, which may bring on the habit of squinting."

It appears as a quality in the senses of hearing and seeing, "that the instrument of each separate sense has a sympathy and similitude to that which giveth the reflection." Thus it has been observed, "that the eye will sympathize with a crystal glass or water, and the ear with caves and such hollow places as are suited to report echo."

Sympathies have been compared to unisons of sound in music. Unisons of sound produce agreeable sympathetic feelings; the reverse produce disagreeable feelings. "All concords and discords of music are (no doubt) sympathies and antipathies of sound." Moreover, "they are said to work as well by report of sound as by motion."

The sense of feeling may be disturbed by any uncommon, though apparently slight, irritation. Thus tickling the sides or soles of the feet will cause laughter; and again, tickling the nostrils will raise sneezing, and on a sudden wonderfully increase the secretion of tears. Both these operations, as sympathies, tend to remove both cause and effect, "by producing a sudden emission of the spirits," and the expulsion (if there should be any) of the offending matter.

The most agreeable as well as odious objects operate in a secondary way, in producing those sympathetic impressions and actions which they commonly give rise to. An increased secretion of saliva often takes place at the sight of a favourite dish; and the running of water from a bottle, or otherwise, will sometimes affect individuals of a particular idiosyncrasy, with an involuntary propensity to void urine.

Many have attempted to account for the remarkable sympathy which takes place between parts of the body seemingly in a great measure unconnected with each other. Most have supposed that the sym-

pathy took place through the brain; that the extremities of the nerves conveying a disagreeable or painful sensation to the medullary part of the brain, affected some part of its fibres adjacent to or connected with the origin of the nerves distributed to some other parts of the body; whence the latter become also affected, and of consequence that part of the body to which they are distributed. In a late treatise†, however, Dr Kirkland has endeavoured to explode this theory, and to establish another. He denies that either the medullary part of the brain or of the nerves consists, as into the present State of Medical surgery. he says, ever saw the extremity of any nerve; nor are any fibres, distinct from blood-vessels, to be seen even by a solar microscope in the medullary substance of the brain or inside of a nerve. He asserts, that the medulla of the brain is a mere mucus, which totally, or almost totally, evaporates with the heat of boiling water, or even in the heat of the common atmosphere in the shade; that this mucus is continued through the nerves, and by them spread out on the muscles, where it appears in its proper form, namely that of a fine transparent mucus. This he proves from observing, that though a muscle may be irritated, either by pricking it or the nerve above it, yet if the mucus which lies on the surface be previously wiped off, no such irritation will take place. The nerves then, according to our author, are only designed to convey this mucus to every part of the body, that, as the brain is the fountain of life, every part may share in the common life of the whole. Hence he is of opinion, that the nervous sympathy does not act from one part of the body through the brain to another; but from one part directly to another by means of the mucus, or substance similar to the brain, with which all the muscles are covered.

Dr Monro, in his observations on the structure and functions of the nervous system, gives it as his opinion, that the nerves are not entirely formed out of the substance of the brain, but receive a considerable addition of matter as they pass through the body; and that the nerves have a peculiar energy of their own independent of the brain. He is also of opinion, that the rest of the brain which is not sent out in nerves serves as a medium between the living principle and the other parts of the body; and that the opposite sides of the encephalon are joined by bundles of fibres: "so that (says he) we seem in a certain degree to perceive the cause of the suffering of all the parts of the nervous system with that of any one part of it, or of the general sympathy of the nerves."

SYMPHONY, in music, properly denotes a concert or concert of several sounds agreeable to the ear, whether vocal or instrumental, called also *harmony*. See HARMONY.

SYMPHYSIS, in anatomy, one of the kinds of junctures or articulation of the bones. See ANATOMY, n° 2, c.

Cutting the SYMPHYSIS of the Pubes. See MIDWIFERY, p. 5032.

SYMPHYTUM, COMFREY; a genus of the monogynia order, belonging to the pentandria class of plants. There are three species; of which the officinale, or common comfrey, is the most remarkable. This

Symposiarch grows naturally in many places of Britain on the sides of rivers and wet ditches. The roots are used in medicine, and are of a mucilaginous nature; the leaves give a grateful flavour to cakes and panadoes. Cows and sheep eat the herb; horses, goats, and swine, refuse it.

Synanthus.

SYMPOSIARCH, in antiquity, the director or manager of an entertainment. This office was sometimes performed by the person at whose charge the entertainment was provided; sometimes by another named by him; and at other times, especially in entertainments provided at the common expence, he was elected by lot or by the suffrages of the guests.

SYMPTOM, in medicine, is defined by Galen to be a preternatural affection which depends upon a disease or follows it. Thus symptoms are diseases produced by an original principal disease. But symptoms are sometimes the effect of symptoms also. A symptom may be a symptom and a disorder at the same time; as when a symptomatic fever is produced by a phlegmon.—A knowledge of the origin and cause of symptoms conduces to confirm the prognosis, and to the certain removal of the disease.

SYMPTOMATICAL, in medicine, is a term often used to denote the difference between the primary and secondary causes in diseases: thus a fever from pain is said to be symptomatical, because it rises from pain only.

SYNÆRESIS, CONTRACTION, in grammar, a figure whereby two syllables are united in one; as *veniens* for *vehemens*.

SYNAGOGUE, a particular assembly of the Jews met to perform the offices of their religion: Also the place wherein they meet. The word is Greek, *συναγωγή*, which literally signifies an assembly or congregation.

SYNARTHROSIS, } See **ANATOMY**, n° 2.

SYNCHONDROSIS, }

SYNCHRONISM denotes the happening of several things at the same time. See **CHRONOLOGY**.

SYNCOPE, **FAINTING**; a deep and sudden swooning, wherein the patient continues without any sensible heat, motion, sense, or respiration, and is seized with a cold sweat over the whole body; all the parts, in the mean time, turning pale and cold as if he was dead.

SYNCOPE, in grammar, an elision or retrenchment of a letter or syllable out of the middle of a word, as *calidus* for *calidulus*.

SYNDIC, in government and commerce, an officer, in divers countries, intrusted with the affairs of a city or other community, who calls meetings, makes representations and solicitations to the ministry, magistracy, &c. according to the exigency of the case.

SYNECDOCHE, in rhetoric, a kind of trope frequent among orators and poets. See **ORATORY**, n° 52.

SYNECPHONESIS, in grammar, a coalition, whereby two syllables are pronounced as one; being much the same as **SYNALOPHA** and **SYNÆRESIS**.

SYNEUROSIS. See **ANATOMY**, n° 2.

SYNGENESIA, (*συν*, together, and *γενεσις*, generation), the name of the 19th class in Linnæus's Sexual Method, consisting of plants in which the antheræ or male organs of generation are united into a cylinder; the filaments on which they are supported being separate and distinct.

SYNGNATHUS, or **PIPE-FISH**, in ichthyology, a

genus of fishes belonging to the order of amphibia **Syngnathus**. There are seven species; of which three are found in the British seas, viz.

Synœcia.

1. The barbarus, or longer pipe-fish. One described by Sir Robert Sibbald, was two feet in length; that examined by Mr Pennant only 16 inches. The nose was an inch long, compressed sidewise, and the end of the lower mandible turned up: the aperture of the mouth was very small.—The irides were red; behind each eye was a deep brown line.—The body, in the thickest part, was about equal to a swan's quill, hexangular from the end of the dorsal fin; from thence to the tail, quadrangular. The belly was slightly carinated, and marked along the middle with a dusky line. Under the tail, commencing at the anus, is a sulcus or groove six inches and a half long, covered by two longitudinal valves, which concealed a multitude of young fish. On crushing this part, hundreds may be observed to crawl out.

2. The acus, or shorter pipe-fish, is thicker than the former, yet it has been seen of the length of 16 inches. The middle of the body in some is hexangular, in others heptangular. The mouth is formed like that of the former: the irides are yellow: close behind the head are the pectoral fins, which are small and short. On the lower part of the back is one narrow fin; beyond the vent the tail commences, which is long and quadrangular. At the extremity is a fin found and radiated. The body is covered with a strong crust, elegantly divided into small compartments. The belly is white; the other parts are brown.

3. The ophidion, or little pipe-fish, seldom exceeds five inches in length, is very slender, and tapers off to a point. It wants both the pectoral and tail fins; is covered with a smooth skin, not with a crust as the two former kinds are. The nose is short, and turns a little up; the eyes are prominent. On the back is one narrow fin.—This species is not viviparous: on the belly of the female is a long hollow, to which adhere the eggs, disposed in two or three rows. They are large, and not numerous. The synonym of *serpent* is used in several languages to express these fish: the French call one species *orouel*, from a sort of snake not unlike the blindworm: the Germans call it *weberschlange*; and the Cornish the *sea adder*.

SYNOCHA, and **SYNOCHUS**, in medicine, the names of two species of continued fever. See **MEDICINE**, n° 274, 279.

SYNOD, in astronomy, a conjunction or conjunction of two or more stars or planets; in the same optical place of the heavens.

SYNOD signifies also a meeting or assembly of ecclesiastical persons concerning matters of religion.

SYNODICAL, something belonging to a synod. Thus, synodical epistles are circular letters written by the synods to the absent prelates and churches; or even those general ones directed to all the faithful, to inform them of what had passed in the synod.

SYNOECIA, in Grecian antiquity, a feast celebrated at Athens in memory of Theseus's having united all the petty communities of Attica into one single commonwealth; the feast whereof was at Athens, where all the assemblies were to be held. This feast was dedicated to Minerva; and, according to the scho-

Synonymous. Scholiast of Thucydides, it was held in the month *Metagitnion*.

Syracuse. **SYNONIMOUS**, is applied to a word or term that has the same import or signification with another.

SYNOVIA, in medicine, a term used by Paracelsus and his school for the nutritious juice proper and peculiar to each part. Thus they talk of the synovia of the joints, of the brain, &c.

SYNTAX, in grammar, the proper construction or due disposition of the words of a language into sentences and phrases. See **GRAMMAR**, and **LANGUAGE**.

SYNTHETIC, or **SYNTHETICAL**, that part of chemistry by which we are taught to compound bodies from the various principles or elements into which they have been resolved by the analytical part.

SYNTHETIC, in logic. See **LOGIC**, n° 117.

SYPHON. See **HYDROSTATICS**, n° 20, 38. Some uncommon phenomena in nature may be accounted for upon the principles of the syphon; as, for instance, that of reciprocating springs. See the article **SPRING**.

SYRACUSE, once a celebrated city of Sicily, and the capital of the island. It was built, according to Thucydides and Strabo, by Archias, one of the Heraclidae, who came from Corinth into Sicily in the second year of the 11th olympiad, deriving its name from a neighbouring marsh named *Syraco*. What form of government first prevailed in the city is not certainly known. Many have supposed it originally to have been governed by kings: but if this was the case, the monarchical government must have continued only for a very short time; since Aristotle, Diodorus Siculus, and Justin, mention it as being very early subject to a democracy. The history, however, is obscure and unimportant till the time of Gelon, when it first began to make a conspicuous figure.

Gelon was born in the city of Gela in Sicily, of the family of Telines, who had been created priest of the infernal gods. He signalized himself in a war carried on by Hippocrates tyrant of Gela against the Syracusans, whom he defeated in a pitched battle, and had well nigh taken their city afterwards. Having thus become very powerful among his countrymen, he soon found means to seize on the sovereignty for himself. In a short time, having put himself at the head of some Syracusan exiles, he marched towards that place, where he was received with loud acclamations by the faction to which they belonged; and by their means obtained possession of the city.

Gelon, in order to people the capital of his new dominions, first demolished the neighbouring city of Camarina, and transplanted the inhabitants to Syracuse. Soon after, entering into a war with the Megareans, he defeated them, took and razed their cities, and in like manner transplanted the people. Syracuse thus became very powerful, and full of inhabitants; and the friendship of Gelon was courted both by Athens and Lacedæmon at the time of the Persian invasion. His assistance, however, was afterwards rejected, as he insisted upon being made commander in chief, or at least of either the fleet or the land-army. In the mean time the Carthaginians had entered into a treaty with the Persians; by which it was agreed, that the former should attack those of the Greek name in Sicily and Italy, in order to divert them from assisting

one another. Sicily was accordingly invaded by the Carthaginians with a vast army; but they were utterly overthrown by Gelon, as is related under the article **CARTHAGE**, n° 7—9. After this victory, the people out of gratitude obliged him to take upon himself the title of king; which till that time he had refused. The decree also passed without opposition, by which the crown was settled on his two brothers Hiero and Thrasylbulus after his death.

The new king, instead of keeping his subjects in greater awe, studied the more to make them happy as he found his power increased; and, according to Diodorus Siculus, was the first man who became more virtuous by being raised to a throne. He was particularly famous for his honesty, truth, and sincerity; is said never to have wronged the meanest of his subjects, nor ever to have promised a thing which he did not perform.

Gelon died in the year 471 B. C. after having reigned three or four years; and was succeeded by his brother Hiero, whose character is differently related by different historians. He was twice engaged in a war with the Agrigentines, and drove from their habitations the people of Catania and Naxos, settling in their room a colony of Syracusians and Peloponnesians. He is highly celebrated in the odes of Pindar; and it is certain that his court was the resort of men of wit and learning, to whom he behaved in the most courteous manner and with the greatest liberality.

In 459 B. C. Hiero was succeeded by Thrasylbulus; who proving a tyrant, was in ten months driven out, and a popular government restored; which continued for the space of 55 years. However, several persons continued for some time to aspire at the sovereign power; and to rid themselves of these aspiring geniuses, the inhabitants made a law not unlike that of the ostracism at Athens. By this law they were to write on a leaf the names of those whom they supposed to be powerful enough to aspire at the crown; and when the leaves were counted, he who had the most suffrages against him was, without further inquiry, banished for five years. This method of weakening the interests of the overgrown citizens was called *petalism*, from the Greek word *πιταλον*, signifying a leaf; but being found to be productive of great inconveniences, by driving out of the country all those who were most capable of governing the commonwealth, the law was repealed soon after it had been enacted.

About this time the Syracusians entered into a war with the Siculi, which terminated in the total subjection of the latter; after which Syracuse became so powerful, that it in a manner gave law to the whole island. The Greek cities indeed enjoyed a perfect liberty; but they all acknowledged Syracuse as their metropolis: by degrees, however, the latter began to assume such an authority over them as was totally inconsistent with liberty; and this occasioned many wars, which involved them in much distress and danger. They began with the Leontines, whose territory they laid waste, and reduced their city to great straits. Leontini was an Athenian colony; and this furnished the Athenians, who had already meditated the conquest of Sicily, with a pretence to attack the Syracusians with their whole force. Under colour of assisting their countrymen, therefore, they sent a fleet

of 250 sail to Sicily : but the Leontines, sensible that their pretended allies aimed at nothing less than the conquest of the whole island, concluded a peace with Syracuse; and the disappointed Athenians vented their rage upon those who had advised and conducted the expedition.

15
A new in-
vasion.

In 416 B. C. a dispute happening between the inhabitants of Egæta and Selinus concerning some lands which the latter had seized, the Egælines applied for assistance to Agrigentum, Syracuse, and even to Carthage. But as none of these states chose to intert themselves in their quarrel, they applied at last to the Athenians, who joyfully accepted of the opportunity of again interfering in the affairs of Sicily. Though the Egælines were but an inconsiderable people, they had engaged to pay all the troops that should be employed in the war; but this appearing doubtful to the Athenians, they sent ambassadors to inquire into the state of the island in general, and particularly that of Egæta. The Egælines imposed on these ambassadors by producing a great number of gold and silver vessels which they had borrowed for the purpose; so that the populace of Athens, dreaming of nothing but conquests to be made without any expence, became oblatinately bent on the war. Nicias, a man of great influence at Athens, attempted to show, that as Athens was then engaged in a dangerous war with Sparta, it was impossible to spare a force sufficient to reduce the island; but the contrary opinion being espoused by Alcibiades, at that time the most eloquent speaker in Athens, Nicias was over-ruled, and obliged to engage in the expedition. The force he required was only 5000 land-forces and 100 galleys, with which, however inadequate to the purpose it may seem, the Athenians were so sure of success, that the officers, before they set sail, had a conference with the senate concerning the disposal of the Sicilians. In this conference it was agreed, that the Selinuntines and Syracusians their supposed allies should be carried off and sold for slaves, and the rest obliged to pay an annual tribute and live according to the Athenian laws.

17
The ground-
less confi-
dence of the Athe-
nians.

With these sanguine expectations the Athenian forces embarked to the number of 7000; for such was their eagerness for the expedition, that 2000 more enlisted themselves than Nicias had required. They first sailed to the island of Egina, and from thence to Corcyra, where they had appointed the place of rendezvous for their allies and the transports. On their arrival, they set sail again, and landed on the coast of Italy, with a view to engage some of the Italian cities in their quarrel; but finding this impossible, they sent some ships to cruise off the coast of Sicily, in order to find out a proper place for landing, and at the same time to know what treasure the Egælines could contribute towards carrying on the war, which had been undertaken for their sake. These, on their return, acquainted the generals, that the Egælines had imposed on them, and were a poor indigent people, who had only 30 talents in their treasury. On this information a council of war was called, in which Nicias gave it as his opinion that they should sail to Selinus, which had been the first occasion of this expedition; and then, if the Egælines performed their promise, and supplied the army with a month's pay,

lines.

to oblige the Selinuntines and Egælines to come to an agreement, and then return to Athens without engaging in such an expensive war. Alcibiades, how-
ever, again opposed Nicias; thinking, it highly dis-
honourable to return home without doing any thing,
after having been at the expence in fitting out an
armament. He therefore urged, that they should
solicit the cities of Sicily to enter into a confederacy
against the Syracusians and Selinuntines; and, in case
they found them disposed to come into their measures,
to attack either Syracuse or Selinus. Another of the
Athenian generals was for laying siege immediately to
Syracuse; but the opinion of Alcibiades prevailing,
they set sail for Sicily. Having accordingly landed
in the island, they reduced several places; but Alci-
biades in the mean time being recalled, Nicias and
Lamachus were left to conduct the war as they best
could. At first they were successful, possessing them-
selves of a strong post, and put the Syracusians to
flight; soon after which they received considerable sup-
plies both of men, money, and provisions, from Athens,
as well as from their Sicilian allies. The Syracusians
also received assistance from the Lacedæmonians under
the command of an experienced officer named Gylippus.
Before these arrived, however, the Athenians had
possessed themselves of an important post named *Epi-
polæ*, which being a very steep hill, flood without the
city and commanded it. Immediately after this the city
was invested in form. The inhabitants made frequent
and vigorous sallies; but were always repulsed with
loss. In one of these sallies Lamachus was slain;
and thus Nicias became sole commander. He then
caused the canals to be cut by which water was
conveyed into the city; upon which the Syracusians
began to think of capitulating. From this, however,
they were soon prevented by the arrival of Gylip-
pus with the Spartan auxiliaries. On this they pre-
pared for making vigorous sallies, in order to facilitate
the entrance of Gylippus. While they were making
these preparations, Gylippus himself appeared at the
head of 3000 foot and 200 horse. Making directly
for Epipolæ, where Nicias had fortified himself in a
castle named *Labdalon*, he drew up his small army
under the walls; and sent an herald to Nicias, letting
him know that he would allow him only five days to
leave Sicily. To this message Nicias returned no an-
swer; but Gylippus soon after attacked the fort,
carried it by storm, and put to the sword all the
Athenians that were in it. This opened him a
way into the city, where he was received with loud
acclamations.

forces to be in readiness to prevent them from effecting their purpose. But as the people were then in the height of their rejoicing for the late victory, they refused to take up arms again until they had rested for some days. On this Hermocrates the general sent to the Athenian camp some horsemen, who were to pass for friends, and advise Nicias to quit his camp, which was well fortified, since the Syracusians lay in ambush for him, and had seized on all the passes leading to the cities of their allies. To this false advice Nicias gave too easy credit, and did not march out till the third day, when his antagonist Hermocrates had prevailed upon his forces to march out. The Athenians and their allies also marched out to the number of no less than 40,000; but finding themselves shut up on all sides, and being obliged to fight their way through every outlet, they soon sunk into the deepest despair. Nicias did his utmost to encourage them; and at last succeeded so far that they marched out in two bodies, both drawn up in proper order. The vanguard led by Nicias continued to keep together, and advanced in good order; but half the rear, commanded by Demosthenes, lost their way in the night, and were obliged to surrender. Nicias being informed of this misfortune, offered to pay the whole expence of the war, provided he was allowed to march off with his men. But this being rejected, he set out, though galled all the way by showers of darts from his enemies. Arriving at a river called *Asmarus*, they rushed into it without any order; in which confusion the Syracusan cavalry attacked them so desperately, that 18,000 perished, and the river for many miles was dyed with their blood. On this occasion the Athenians were so pressed with thirst, that, unmindful of their danger, they drank the waters of the river all bloody as they were, which gave their enemies the better opportunity of slaughtering them without resistance. The remainder surrendered, on the single condition of having their lives saved; but the terms were shamefully broke by the Syracusians. The generals were first ignominiously whipt, and then put to death: the common soldiers were thrust down into quarries, where they were allowed only two small measures of flour and one of water a day; and where, being crowded upon one another, they suffered inexpressible miseries for many months. Most of them perished by this cruel treatment, and the few who survived were sold for slaves.

The war was scarce ended, when a new and formidable invasion by the Carthaginians took place; but the event of that expedition was as unfortunate to the Carthaginians as the former had been, of which a particular account is given under the article *CARTHAGE*, n^o 12. *et seq.*

In the mean time, however, a considerable revolution had happened in Syracuse. The city of Agrigentum had been taken by the Carthaginians, and of the few inhabitants who escaped, some fled to Syracuse, where they accused the Syracusan commanders of having betrayed the city into the hands of the enemy. Dionysius, a man of great valour and address, but who had become very obnoxious to the populace, took this opportunity of attempting to retrieve his credit. He therefore supported the accusations brought against his countrymen by the Agrigentines, and even impeached the magistrates as

having a secret intelligence with the enemy, and attempting to introduce an oligarchy. As his speech was entirely levelled against the more wealthy citizens, it was very agreeable to the lower class: the commanders were instantly degraded; and others, among whom was Dionysius, were appointed. Having once gained this point, he began to consider how he might get all his colleagues turned out. For this purpose he never joined in any council of war with the other commanders, nor imparted to them his resolutions, giving out that he could not trust them, and that they had more regard for their own interest than the welfare of their country. But while he was proceeding in this manner, the more prudent part of the citizens, perceiving what he aimed at, complained of him to the senate and magistrates, and fined him as a disturber of the public peace. According to the laws, the fine was to be paid before he could speak in public, and the circumstances of Dionysius did not allow him to discharge it. In this dilemma he was assisted by Philistus the historian, a man of great wealth, who not only paid this fine for him, but encouraged him to speak his mind freely, as it became a zealous citizen to do, promising to pay all the fines that should be laid upon him.

Being extricated out of this difficulty, Dionysius next proceeded to inveigh, with all the eloquence he was master of, against those who by means of their power or interest were able to oppose his designs, and by degrees brought them into discredit. His next scheme was to get those exiles recalled whom the nobility had banished at different times; as thinking that they would support him with all their power, as well out of gratitude as out of hatred to the opposite party. Having gained this point also, he next found means to ingratiate himself with the soldiery to such a degree, that, under pretence of taking proper measures for resisting the Carthaginians, he was chosen commander in chief, with absolute and unlimited power. This was no sooner done, than, pretending that his life was in danger, he chose out 1000 men for his guard, whom he attached to his interest by great promises. As no person durst now oppose him, he possessed himself of the citadel, where all the arms and provisions were kept; after which he publicly took the title of king of Syracuse in the year 404 B. C.

The Syracusians did not tamely submit to their new master: but Dionysius managed matters so well, that their frequent revolts answered no other purpose than more certainly to entail slavery on themselves; and he was allowed to possess the throne without much opposition till his death, which happened in the year 366 B. C.

On the death of Dionysius, he was succeeded by his son, called also *Dionysius*. He was naturally of a mild and peaceable temper, averse from cruelty, and inclined to learning; but his father, to whom all merit, even in his own children, gave umbrage, stifted as far as possible his good qualities, by a mean and obscure education. He no sooner ascended the throne, than Dion, brother to Aristomache the other wife of Dionysius the elder, undertook to correct the faults of his education, and to inspire him with thoughts suitable to the high station in which he was placed: For this purpose he

sent for the philosopher Plato, under whose care he immediately put the young king. This instantly produced a reformation on Dionysius; but the courtiers, dreading the effects of the philosopher's instructions, prevailed on him to banish Dion, and to keep Plato himself in a kind of imprisonment in the citadel. At last, however, he set him at liberty; upon which Plato returned to his own country.

Dion, in the mean time, visited several of the Grecian cities, and at last took up his residence in Athens; but the honours which were every where paid him, raised such jealousies in the breast of the tyrant, that he stopped his revenue, and caused it to be paid into his own treasury. In a short time, Dionysius again sent for Plato; but finding it impossible to dissolve the friendship between him and Dion, disgraced, and placed him in a very dangerous situation, in the midst of assassins who hated him. Not daring, however, to offer him any violence, he allowed him soon after to depart; revenging himself on Dion, whose estate he sold, and gave his wife Arete in marriage to Timocrates one of his own flatterers.

Dion now resolved to revenge himself on the tyrant for the many injuries he had sustained, and at once to deliver his country from the oppression under which it groaned. He began with raising foreign troops privately, by proper agents, for the better execution of his design. Many Syracusians of distinction entered into his scheme, and gave him intelligence of what passed in the city: but of the exiles, of whom there were upwards of 1000 dispersed up and down Greece, only 25 joined him; so much were they awed by the dread of the tyrant. The troops were assembled at the island of Zacynthus, in number only about 800; but who had all been tried on many occasions, were well disciplined, and capable of animating by their example the forces which Dion hoped to find in Sicily. When they were about to set sail, Dion acquainted them with his design, the boldness of which at first occasioned no small contention among them; but Dion soon removed their fears, by telling them that he did not lead them as soldiers, but as officers, to put them at the head of the Syracusians and all the people of Sicily, who were ready to receive them with open arms. Having then embarked in two small trading vessels, they arrived in 12 days at Cape Pachynum near Syracuse. Their pilot advised them to land immediately, lest they should be overtaken by a violent storm, which he perceived was approaching; but Dion, judging it improper to land so near the enemy, commanded him to put to sea again and double the Cape.—This was no sooner done than the storm came on; and the two vessels were driven on the coast of Africa, where they were in great danger of being lost. At last they arrived at the port of Minoa, not far from Agrigentum. Here they received intelligence that Dionysius had set sail for Italy, attended by a fleet of 80 galleys. On this Dion resolved to take advantage of the tyrant's absence; and immediately set sail for Syracuse. On his march he prevailed upon the inhabitants of Agrigentum, Gela, Camarina, and other cities, to join him. As soon as he entered the territories of Syracuse, multitudes flocked to him; and as nobody appeared to oppose him, he boldly entered the city, where he quickly found himself at the head of 50,000

men. As soon as he had landed in Sicily, Timocrates, to whom his wife Arete had been given by Dionysius, and to whom the care of the city had been left, dispatched a courier to let the tyrant know the danger in which he was. The messenger, when almost at his journey's end, found himself so much oppressed by fatigue, that he could not help lying down on the ground to take some rest. In the mean time, a wolf, smelling some meat which he had in his wallet, came to the place, and carried off the bag in which was the meat; together with the dispatches. By this means Dionysius was prevented from receiving a timely account of Dion's arrival; so that when he entered the citadel by sea, seven days after Dion's arrival, he found his affairs in a desperate situation. Upon this he had recourse to artifice; and having amused the Syracusians by a feigned negotiation, until he observed that they kept a negligent guard, he attacked them all at once with such fury, that he had almost taken the city. But Dion encouraged the soldiers by his example so much, that he at last obtained a complete victory; for which they presented him with a crown of gold.

It was not long, however, before the ungrateful Syracusians began to think of conferring quite different rewards on their benefactor. Dionysius had addressed to render him suspected by the multitude; at the same time that Heracles, an excellent officer, but a secret enemy to Dion, did all that lay in his power to sink his credit. In a short time Dionysius was obliged to fly into Italy: after which Heracles, in order to ingratiate himself with the populace, proposed a new division of lands; insinuating, that they could never enjoy perfect liberty as long as there was so much inequality in wealth and power among the citizens. This scheme was opposed by Dion, in consequence of which a general combination was formed against him; and he was deserted by all, excepting the foreign troops whom he had brought with him into the island. The Syracusians solicited even these to abandon the cause of their general: but their offers were rejected with disdain; and Dion, with his faithful adherents, getting clear of the tumultuous and riotous populace, took the road to Leontini. The rabble pursued him, but were soon driven back; and Dion resided for some time at Leontini, where he was received with all the respect due to his character.

In the mean time the citadel still continued in the hands of the adherents of Dionysius. Being blocked up on all sides, they were reduced to great straits, and were actually making proposals of capitulation, when Nymphis, an experienced general, and greatly attached to Dionysius, appeared with a numerous squadron of galleys, and a large fleet of transports laden with provisions. The general landed his men, and got them into the citadel; but almost all his galleys and ships laden with corn were sunk or taken. This victory proved the ruin of the Syracusians; for, giving themselves up to feasting and debauchery, the enemy sallied out in the night-time from the citadel, and massacred the citizens without mercy. Being thus made sensible of the error they had committed, an embassy was sent to Dion, intreating him to return and save the city a second time. To this he agreed without hesitation, and instantly set out on his march; but in the mean time,

time, as the soldiers of Dionysius, fatiated with slaughter, had retired into their fortresses, the ungrateful Syracusians began to repent of their having sent an embassy to Dion. The chief commanders, therefore, sent messengers to stop his march; but as some of his friends sent deputies to him at the same time, desiring him to pay no regard to the former message, he proceeded on his journey. The insatuated multitude seized the gates in order to dispute his entrance; but they paid dear for their frenzy. The Dionysians again sallied out upon them, and made such slaughter that one would have thought they had left none alive in the city. As the troops of the tyrant well knew that Dion was hastening to the relief of the city, they used their utmost endeavours to destroy it entirely before his arrival; for, after they had murdered all the inhabitants they could find, they set fire to the houses, by which great numbers perished. During this confusion Dion unexpectedly arrived; and having briskly attacked the enemy, at last defeated them with great slaughter, driving the remainder into the citadel. During the rest of the night, instead of refreshing themselves after their fatigues, they assisted in extinguishing the fire; which was not done without great danger and difficulty. The citadel soon after surrendered; and Dion allowed Apollocrates the tyrant's son, who commanded there, to retire with five galleys to his father. As soon as Dion entered the citadel, he was met by his sister and wife Arete, whom he received with affection, notwithstanding her having lived so long with Timocrates. He then left the Syracusians in possession of the citadel, rewarded his followers, dismissed his guards, and continued to live like a private citizen.

As soon as Dion had got possession of the city, Heraclides had submitted to him, and been received into favour; but as his seditious and turbulent behaviour still continued, Dion at last gave orders to put him to death. This action, however necessary, so affected the mind of Dion, that he became melancholy; and ever after imagined himself haunted by a frightful spectre, resembling a woman of gigantic stature, with the haggard looks and air of a fury. In a short time after, he lost his life, through the base treachery of Calippus, or Gylippus, who pretended to be his intimate friend, and who immediately after caused his wife and sister to be carried to prison.

Calippus having thus removed Dion, soon made himself master of Syracuse, where he committed all manner of cruelties; but was driven out, and forced to fly to Rhegium, where he was murdered with the same dagger which had killed Dion. In 350 B. C. Dionysius again made himself master of Syracuse; and being exasperated by his past misfortunes, tyrannized worse than ever. The Syracusians first had recourse to Ictas tyrant of Leontini; but as the Carthaginians took this opportunity to invade them with a powerful fleet and army, they were obliged to apply to the Corinthians. By them Timoleon, a celebrated commander, was sent to the assistance of the Syracusians, whom he found in a very distressed situation; Ictas being master of the city, the Carthaginians of the harbour, and Dionysius of the citadel. As all parties were equally the enemies of Dionysius, he found it impossible to hold out, and therefore surrendered himself to Timo-

Vol. X.

leon, by whom he was sent to Corinth; where at last he was reduced to the necessity of teaching a school for his support.

After the expulsion of the tyrant, Timoleon withdrew to Catana, leaving only 400 Corinthians, under the command of an experienced officer named Leon, to guard the citadel. These were immediately besieged by Ictas and the Carthaginians, but Timoleon found means to relieve them in spite of all opposition; and having dispersed emissaries through the army of Mago the Carthaginian general, exhorting the mercenary Greeks to forsake him, he was so much intimidated, that in spite of all the remonstrances Ictas could make, he set sail for Africa, leaving his colleague to carry on the war in the best manner he could.

The day after the departure of Mago, Timoleon assaulted the city so briskly, that the troops of Ictas were driven from the walls, and the Corinthians became masters of the place. Timoleon, by found of trumpet, invited the inhabitants to come and assist in demolishing the citadel and other castles, which he called the *nest of tyrants*; after which he caused edifices to be erected in the place where the citadel had stood, for the administration of justice. He found the city in a most miserable situation: for many having perished in the wars and seditions, and others having fled to avoid the oppression of tyrants, Syracuse, once so wealthy and populous, was now become almost a desert; inasmuch that the horses were fed on the grass which grew on the market-place. Timoleon supplied the city with inhabitants from Corinth and other cities of Greece, at the same time that great multitudes from Italy and the other parts of Sicily resorted thither. Timoleon distributed the lands among them *gratis*; but sold the houses, and with the money arising from the sale established a fund for the support of the poor. Having thus restored Syracuse, he in like manner delivered all the Greek cities of Sicily from the tyrants who had taken possession of them, all of whom he put to death. After this he resigned his authority, and led a retired life, honoured in the highest degree by the Syracusians, and by all the cities in Sicily. After his death he was honoured as a god; the expense of his funeral was defrayed by the public; sports, with horse-races and gymnastic exercises, were held annually on the day of his death; and it was decreed, that whenever the Syracusians were at war with the barbarians, they should send to Corinth for a general.

For 20 years the Syracusians enjoyed the fruits of Timoleon's victories; but new disturbances arising, in a short time another tyrant started up, who exceeded all that had gone before him in cruelty and other vices. This was the celebrated Agathocles, of whose exploits against the Carthaginians a full account is given under the article CARTHAGE, n° 33—53. He was poisoned by one Mænon in the year 289 B. C. after having reigned 28 years and lived 95. A succession of tyrants followed, till at last the city, being held by two rivals, Tæmon and Sosistratus, who made war within the very walls, Pyrrhus king of Epirus was invited into Sicily, in order to put an end to these distractions. He willingly complied with the invitation; and was everywhere received with loud acclamations, as the deliverer not only of Syracuse, but of all Sicily. As he had a

42 R

fine

Syracuse. fine army of 30,000 foot and 5000 horse, with a fleet of 200 sail, he drove the Carthaginians from place to place, till he left them only the two strong posts of Eryx and Lilybæum. The former of these he took by assault, and was himself the first man who mounted the walls, after having killed a great number of Africans with his own hand. The Mamertines likewise, who had conquered a considerable part of the island, were everywhere defeated and driven out, till at last they were shut up in the city of Messina. The Carthaginians, alarmed at the rapidity of his conquests, sent ambassadors with proposals of peace upon very advantageous terms; but Pyrrhus, puffed up with the expectation of reducing the whole island, refused to hearken to any terms unless they would instantly abandon it. So firm was he in the belief of this, that he caused his son take upon him the title of *king of Sicily*; but in the mean time, having displeased the Sicilians by his arbitrary behaviour, they deserted from him in such numbers that he was glad to set out for Italy, for which retreat the embassies he received from the Samnites, Tarentines, and other Italians, furnished him with an honourable pretext. He embarked in the ships which he had brought with him from Italy; but was met at sea by the Carthaginians, who sunk 70 of his vessels, and dispersed or took the rest; so that he saved himself in Italy only with 12 vessels, the poor remains of a fleet of 200 sail. No sooner were the Mamertines apprised of his departure, than they dispatched a body of 18,000 men to harass him after his landing. These, having passed the straits before him, posted themselves in the road which Pyrrhus must take in marching by land to Tarentum; and concealing themselves among woods and rocks, attacked him unexpectedly, and with great resolution. But Pyrrhus behaved on this occasion with his usual bravery. The attack being made on his rear, he hastened thither, and made a dreadful slaughter of the enemy, till a wound on his head obliged him to retire. As he was supposed to be disabled by this wound, a proud Mamertine, of an extraordinary size, and shining in bright armour, advanced, and with a loud voice challenged the king of Epirus, if he was yet alive, to a single combat. Pyrrhus immediately turned about, and making a dreadful appearance by reason of the blood which ran down his face, flew at this new champion, on whose head he discharged such a furious blow, that he cleft his body asunder; one half falling to the right, and the other to the left. This incredible feat, which has since been ascribed to other warriors, perhaps with as much truth as to Pyrrhus, so much intimidated the Mamertines, that they allowed the Epirots to continue their march unmolested.

59 Harassed by the Mamertines.

60 Astonishing exploit of Pyrrhus.

61 Hiero chosen general of the Syracusan forces.

After the departure of Pyrrhus, Hiero the son of Hierocles, a descendant of Gelon the first king of Syracuse, was chosen general of the forces, along with another named *Artemidorus*. The two generals had nothing more at heart than to put an end to the confusion and disorder which reigned in the city; for which reason they entered it at the head of their forces. On this occasion Hiero discovered extraordinary talents for government. By mere dint of insinuation and address, without shedding blood or hurting a single citizen, he calmed the minds of the people; reconciled the factions; and so gained the affections of

all, that he was invested with the whole civil as well as military power in the state. Soon after this, he married the daughter of one of the first citizens; and having distinguished himself by his exploits against the Mamertines, was unanimously elected king of Syracuse, in the year 265 B.C.

Some time after Hiero's accession to the throne, he again defeated the Mamertines, and reduced them to such straits, that they were obliged to call in the Romans to their assistance. The consequences of this have been fully related under the articles *ROME* and *CARTHAGE*. Hiero, who had allied himself with the Carthaginians, being himself defeated by the Romans, and finding his allies unable to protect him against the power of that republic, concluded an alliance with them; and continued faithful to them even in the time of the second Punic war, when they were in the greatest distress. In his reign flourished the celebrated mathematician Archimedes, whose genius he employed in fortifying the city of Syracuse, by innumerable machines, in such a manner as rendered it absolutely impregnable to every method of attack known at that time.

Hiero died in the year 211 B.C. and was succeeded by his grandson Hieronymus; but he imprudently forsook the counsels of his grandfather, and entered into an alliance with the Carthaginians. Soon after this he was murdered, in consequence of his tyranny and cruelty, and the greatest disorders took place in the city; which Hannibal, though then in Italy, found means to foment, in hopes of keeping the Syracusians in his interest. This indeed he effected; but as his own affairs in Italy began to decline*, he could not prevent Marcellus from landing in Sicily with a formidable army, which the Sicilians could by no means resist. Syracuse was soon invested; but the machines invented by Archimedes baffled all attempts to take it by assault. It was 22 miles in compass, and consisted properly of five cities in one, viz. *Ortygia*, *Achradine*, *Tyche*, *Neapolis*, and *Epipolæ*—*Ortygia* was a small island very near the continent, and might be called the *citadel of Syracuse*, being joined to Achradine by a bridge. The immense preparations which the consul had made for taking the city by storm, could not have failed to accomplish his purpose, had the place been otherwise defended than by the contrivance of Archimedes. The Roman fleet consisted of 60 quinqueremes, besides a far greater number of other ships. The decks were covered with soldiers armed with darts, slings, and bows, to drive the besieged from the ramparts, which on the side of Achradine were washed by the sea, and to facilitate the approach to the walls. But a machine of Marcellus's own invention was what he chiefly depended on. He had fastened together sidewise eight galleys of different lengths, which made but one large body, and were rowed only by the oars of the outermost galleys. These eight galleys thus joined, served only as a basis for a machine, which was raised up higher than the highest towers of the walls, and had at the top a platform guarded with parapets in front, and on each side. This machine was called a *sambuca*, from its resemblance to a musical instrument of that name, not unlike an harp. The consul's design was to bring his *sambuca* to the foot of the walls of Achradine; but, while

it was at a considerable distance (and it advanced very slow, being moved only by two ranks of rowers), Archimedes discharged from one of his engines a vast stone, weighing, according to Plutarch's account, 1250 pounds, then a second, and immediately after a third; all which, falling upon the sambuca with a dreadful noise, broke its supports, and gave the galleys upon which it stood such a violent shock that they parted, and the machine which Marcellus had raised upon them at a vast trouble and expence, was battered to pieces. At the same time several other machines, which were not visible without the walls, and consequently did not lessen the confidence of the Romans in the assault, played incessantly upon their ships, and overwhelmed them with showers of stones, rafters, and beams pointed with iron; inasmuch that Marcellus, being at a loss what to do, retired with all possible haste, and sent orders to his land-forces to do the same; for the attack on the land-side was attended with no better success, the ranks being broken and thrown into the utmost confusion by the stones and darts, which flew with such noise, force, and rapidity, that they struck the Romans with terror, and dashed all to pieces before them.

Marcellus, surpris'd, though not discouraged, at this artificial storm, which he did not expect, held a council of war, in which it was resolv'd, the next day before sun-rise, to come up close under the wall, and keep there. They were in hopes by this means to secure themselves against this terrible storm of stones and darts which fell on the ships when at a distance. But Archimedes had prepared engines which were adapted to all distances. When the Romans therefore had brought their ships close under the wall, and thought themselves well covered, they were unexpectedly overwhelmed with a new shower of darts and stones, which fell perpendicularly on their heads, and obliged them to retire with great precipitation. But they were no sooner got at some distance, than a new shower of darts overtook them, which made a dreadful havoc of the men, while stones of an immense weight, discharged from other machines, either disabled or broke in pieces most of their galleys. This loss they sustained, without being able to revenge it in the least on the enemy. For Archimedes had placed most of his engines behind the walls, and not only out of the reach, but even out of the sight, of the enemy; so that the Romans were repulsed with a dreadful slaughter, without seeing the hand that occasioned it; as if they had been fighting, to use Plutarch's expression, not with men, but with the gods themselves. What most harraised the Romans in the attack by sea, was a sort of crow with iron claws, fastened to a long chain, which was let down by a kind of lever. The weight of the iron made it fall with great violence, and drove it into the planks of the galleys. Then the besieged, by a great weight of lead at the other end of the lever, weighed it down, and consequently raised up the iron of the crow in proportion, and with it the prow of the galley to which it was fastened, sinking the poop at the same time into the water. After this the crow letting go its hold all of a sudden, the prow of the galley fell with such force into the sea, that the whole vessel was filled with water, and sunk. At other times the machines, dragging ships to the shore by

hooks, dashed them to pieces against the points of the rocks which projected under the walls. Other vessels were quite lifted up into the air, there whirled about with incredible rapidity, and then let fall into the sea, and sunk, with all that were in them. How these stupendous works were effected, few, if any, have hitherto been able to comprehend.

The troops under the command of Appius suffered no less in this second attack than the fleet. In the whole space of ground which the army, when formed, took up, the last files as well as the first were overwhelmed with showers of darts and flints, against which they could not possibly defend themselves. When they had with infinite trouble brought the mantelets and covered galleries, under which they were to work the rams, near the foot of the wall, Archimedes discharged such large beams and stones upon them as crushed them to pieces. If any brave Roman ventured to draw too near the wall, iron hooks were immediately let down from above, which, taking hold of his cloaths or some part of his body, lifted him up in the air and dashed out his brains with the fall. Marcellus, though at a loss what to do, could not however forbear expressing himself with pleasantry: Shall we persist, said he to his workmen, in making war upon this Briareus, upon this giant with an hundred hands? But the soldiers were so terrified, that if they saw upon the walls only a small cord, or the least piece of wood, they immediately turned their backs and fled, crying out, that Archimedes was going to discharge some dreadful machine upon them.

The consuls, finding themselves thus defeated in every attempt, turned the siege into a blockade, re-duced most of the other places in the island, and defeated the forces which were sent against them; and at last Marcellus made himself master of Syracuse itself, of which the following account is given by Mr Hooke. "He took the opportunity of a festival, when the soldiers and citizens had drunk plentifully, to make a detachment scale the walls of Tyche, and that part of it which was nearest to Epipolæ, and which was ill guarded. He presently after possessed himself of Epipolæ; whereupon the inhabitants of Neapolis, as well as Tyche, sent deputies to him, and submitted. Marcellus granted life and liberty to all of free condition, but gave up those quarters of the city to be plundered.

"Notwithstanding this, there was a great deal yet to do. Achradina and Ortigia, which were strongly fortified, still held out; Hippocrates and Himilco arrived with their troops to the relief of the besieged; and the Romans were forced to exert all their bravery and skill to maintain the advantages they had gained.

"But now a plague made terrible havoc in both armies. At the first breaking out of the pestilence, the Sicilians, who served under Hippocrates and Himilco, disbanded themselves, and returned to their respective homes; but all the Carthaginian soldiers perished, together with those two generals. The Romans suffered less by the infection; because, having been a long time before Syracuse, they were seasoned to the air and water of the country.

"About this time Bomilcar arrived on the coast of Sicily from Carthage with a fleet of 130 galleys and 700 ships of burden; but was long hindered by con-

trary winds from doubling the cape of Pachynum. Epicydes, fearing the Carthaginian might sail back to Africa, left the command of Achradina to the generals of the mercenaries, and went to Bomilcar, in order to persuade him to fight the Roman fleet. The admiral would not engage, but failed away to Tarentum with all his galleys, ordering his ships of burden to return to Africa. Epicydes, thus frustrated of his hopes, and knowing himself unable to defend a city already half taken, retired to Agrigentum; whereupon the Syracusians massacred the commanders appointed by him, chose new pretors to govern in the town, and sent deputies to Marcellus to treat of peace. In the mean time the deserters, fearing to be given up to the vengeance of the Romans, persuaded the mercenaries that they also would have the same fate. Instantly the soldiers ran to arms, put to death the new pretors, together with many of the Syracusians, and plundered part of the city. After this slaughter they chose six generals, three to command in Achradina, and three in Ortygia. Upon the return of the deputies from Marcellus, the mercenaries finding that their case was different from that of the deserters, and that there was no design against their lives, became perfectly satisfied, and the negociation went on. During the course of the treaty, Marcellus found means to corrupt Mericus, a Spaniard, one of the six generals chosen by the soldiers, and engaged him to admit the Romans into that part of the city where he commanded. Mericus, the better to accomplish this design, feigned an extraordinary zeal for the preservation of that place; pretended not to like that deputies should have leave to go out and in at pleasure; and proposed, that for the greater security of the town, each general should have a distinct quarter assigned him, and be responsible for any neglect of duty in it. The motion was agreed to; and upon the division, that district of Ortygia which extended from the fountain of Arethusa to the mouth of the great port fell to his care. Marcellus, informed of what was done, took his measures accordingly. He sent a body of troops to that side where Mericus commanded, and the Spaniard admitted them at the gate of Arethusa. At the same time the proconsul ordered a false attack to be made on Achradina; which drawing almost all the soldiers of the garrison thither, Ortygia was in a manner left defenceless. Foreseeing this, he had detached another party of soldiers to take advantage of it. These entered Ortygia almost without fighting; upon which the deserters made their escape, the Romans giving them way; and the Syracusians in Achradina, thus delivered from the fear of the deserters, immediately opened their gates to Marcellus, who thereby became master of the whole city.

72
The city
plundered,
and Archi-
medes kill-
ed.

“And now the conqueror, who is said to have wept during the siege with compassion for the inhabitants, gave up both Ortygia and Achradina to be plundered by his army, after he had secured the late king's treasures for the use of his republic, and the statues, paintings, and principal ornaments of Syracuse to illustrate his triumph. The soldiers had orders to spare the lives of the citizens; but they were cruel in their avarice, slew many of them, and among the rest the incomparable Archimedes. He was very in-

tent on a demonstration in geometry, and calmly drawing his lines, when a soldier entered the room, and clapped a sword to his throat. “Hold! (said Archimedes), one moment, and my demonstration will be finished.” But the soldier, equally regardless of his prayer and his demonstration, killed him instantly. There are different accounts of the manner of his death; but all agree that Marcellus regretted it extremely, and showed a singular favour to his relations for his sake.”

The city of Syracuse continued subject to the western empire till its declension, when the island of Sicily, being ravaged by different barbarians, the capital also underwent various revolutions; till at last, in the 9th century, it was so destroyed by the Saracens, that very few traces of its ancient grandeur are now to be seen.

by the Sa-
racens.

SYRIA, a very ancient kingdom of Asia, lying between the Mediterranean on the west, the Euphrates on the east, and Arabia Deserta, Phœnice, and Palestine on the south.

In ancient times this country was called *Aram*, from Aram the youngest son of Shem, who settled here; but in process of time the name came to be changed into *Syria*, from one *Syrus*, according to some; tho' others think it is only a contraction of the word *Assyria*. At first it was undoubtedly parcelled out into several petty states; all of which seem afterwards to have been reduced under subjection to the four principal ones, Zobah, Damascus, Hamath, and Geshur. Afterwards the whole country was divided into two parts only, viz. Cœle Syria and Phœnicia; though the Phœnicians, Idumæans, Jews, Gazites, and Azotites, or the whole country of the Philistines, was included. After the death of Alexander, Syria, in the great extent of the word, was divided, according to Strabo, into Comagene, Seleucia of Syria, Cœle Syria, Phœnicia on the sea-coast, and Judea in the mid-land. Ptolemy, however subdivides these; and in the proper Syria reckons only Comagene, Pieria, Cyrristrica or Cyrrhætica, Seleucia, Cassiotes or Castotes, Chalybonitis, Chalcidice or Chalcidene, Apamene, Laodicene, Phœnicia Mediterranea, Cœle Syria and Palmyrene.

Names, di-
visions, &c.
of ancient
Syria.

The history of the ancient Syrians, till the time of their being carried away by the kings of Assyria, is totally unknown, excepting a few particulars which may be gathered from scripture, and which it is needless here to repeat. During the continuance of the Assyrian, Babylonian, and Persian monarchies, the history of this country affords nothing remarkable; but after the death of Alexander, it gave name to a very considerable empire, which makes a conspicuous figure in ancient history. At this time, however, it was not confined to Syria properly so called, but comprehended all those vast provinces of the Upper Asia which formed the Persian empire; being, in its full extent, bounded by the Mediterranean upon one side, and the river Indus on the other. The first king was Seleucus, one of the generals of Alexander the Great; who, after the death of that conqueror, Alexander being made governor of Babylon, was tempted, by the example of Alexander's other captains, to set up for himself. Eumenes, who had sincerely at heart the interest of Alexander's family, solicited his assistance against

against Antigonus, who had openly revolted; but Seleucus not only refused this assistance, but attempted to destroy Eumenes himself with his whole army, by cutting the sluices of the Euphrates, and laying under water the whole plain where they were encamped. Eumenes, however, found means to escape the danger without the loss of a man. Upon this Seleucus endeavoured to gain over his troops: but finding that impossible, he made a truce with Eumenes, and granted him a safe passage through his province; but at the same time sent an express to Antigonus, desiring him to fall upon him before he was joined by the governors of Upper Asia. Antigonus did not fail to follow his advice; but having prevailed against Eumenes through treachery, he next thought of bringing Seleucus himself under subjection. On his return to Babylon, therefore, after having been feasted with his whole army by Seleucus, he demanded of him an account of the revenues of his province. Receiving an unfavourable answer to this question, Antigonus was so much exasperated, that Seleucus, not thinking himself a match for him at that time, thought proper to fly into Egypt.

78
Attempts
the recovery
of Babylon
with a very slender
force.

By the flight of Seleucus, Antigonus was left master of all his provinces; but his son Demetrius being afterwards defeated by Ptolemy at Gaza, Seleucus began to think of recovering what he had lost. Being furnished by Ptolemy with 1000 foot and 200 horse, he set out with that slender force to attempt the recovery of Babylon. Nothing could have a more desperate appearance than this undertaking; yet Seleucus was not discouraged. On his arrival at Carrhæ in Mesopotamia, partly by force and partly by persuasion, he prevailed on the Macedonians who garrisoned that place to revolt from Antigonus and join him. Being thus reinforced, he entered the territories of Babylon, where new supplies were continually added to his army; his ancient subjects flocking to him from all parts, and declaring themselves ready to stand by him with their lives and fortunes. This happened in consequence of the lenity with which they had been treated by Seleucus; whereas Antigonus was universally detested on account of his severity.—As he approached the city, those who favoured Antigonus retired into the citadel, but were obliged to surrender; and in that fortress Seleucus found his children, friends, and domestics, whom Antigonus had kept prisoners ever since his flight into Egypt.

and reduces
Media and
Susiana.

Seleucus having thus made himself master of Babylon, in the year 312 B. C. began to prepare for encountering Antigonus, who he knew would soon attack him with all his force. Nicanor, governor of Media under Antigonus, first advanced against him at the head of 10,000 foot and 7000 horse; but Seleucus, with only 3000 foot and 400 horse, having drawn him into an ambush, cut off almost the whole of his army, and such of the soldiers as had escaped the slaughter willingly enlisted under his banner.

The consequence of this victory was the submission of all Media and Susiana; which alarming Antigonus, he sent his son Demetrius with an army of 5000 Macedonian foot, 10,000 mercenaries, and 4000 horse. Seleucus was then in Media; and Patrocles, whom he had left to take care of Babylon, finding his force

inadequate to that purpose, compelled the inhabitants to leave the city and disperse themselves in the adjacent countries, while he himself, with what troops he had, retired into two forts which he thought could easily be defended. When therefore Demetrius entered Babylon, he was surprised to find it deserted, upon which he instantly attacked the forts. One was quickly reduced; but as the other held out till the expiration of the time which had been allowed him by his father, he left 5000 foot and 1000 horse under the command of Archelaus to carry on the siege. With the rest he marched away, suffering his soldiers to live at discretion as he went along; which so provoked the Babylonians, that they were ever after attached to Seleucus as if he had been their natural prince.

On the return of Seleucus to Babylon, he easily drove out the troops left by Antigonus, recovered the castle which he had garrisoned, and settled his authority on such a firm foundation that it could never afterwards be moved. Having then marched again into Media, he defeated and killed with his own hand Nicanor, or Nicator, whom Antigonus had sent against him; after which, having settled the affairs of Media, he reduced all Persia, Bactria, and Hyrcania, subjecting to his new empire these and all the other provinces on this side the Indus which had been conquered.

Seleucus being now master of all the countries which lie between the Euphrates and the Indus, took the title of king of Babylon and Media. But, not satisfied with these possessions, ample as they were, he crossed the Indus, in order to conquer those regions which had submitted to Alexander beyond that river. But, during the time that the generals of Alexander had been making war upon his family and upon one another, one Sandracottus, a native of India, had driven out the Macedonians, and made himself master of the whole country. He opposed Seleucus with an army of 600,000 men, and a prodigious number of elephants; which intimidated the Macedonian so much, that he offered to leave Sandrocottus in quiet possession of his dominions, provided he would furnish him with 500 elephants. To this Sandrocottus readily assented; upon which Seleucus marched back into the west against Antigonus, and, in conjunction with Lysimachus and Ptolemy, engaged and totally defeated and killed him at Ipsus. After this Seleucus marched into Upper Syria, which he reduced entirely, and built the city of Antioch on the Orontes. In the same country he built several other cities; one of which he called *Seleucia*, from his own name; another *Apamea*, from his wife Apamea, the daughter of one Artabazus a Persian; and a third *Laodicea*, from his mother Laodice. He first entered into an alliance with Demetrius, and married Stratonice his daughter; but soon after assisted Lysimachus and Ptolemy to deprive him of the best part of his dominions. Thus Demetrius being reduced so low that he could give him no farther jealousy, Seleucus betook himself to the building of another city, which he called likewise *Seleucia*, and which stood on the place where the city of Bagdad now stands. Besides these, he built a great many others; 16 of which he called *Antioch*, from the name of his brother Antiochus; nine *Seleucia*, from his own name; three

Apamea, from *Apama* his first wife; one *Stratonicea*, from his second wife *Stratonice*; and six *Laodicea*, from his mother *Laodice*.

In 284 *Seleucus* entered into a war with *Lyfimachus*, with whom he had hitherto lived in strict amity. Out of 36 general officers left by *Alexander the Great*, they two only survived, and both were upwards of 70 years old. Nevertheless they were both filled with the ambition and animosity of young men. The two armies met at a place called *Eurepedion* in *Phrygia*, where an obstinate engagement took place. Victory was long doubtful: but at last *Lyfimachus* was run through with a spear, and died on the spot; on which his troops betook themselves to flight, and left *Seleucus* master of their baggage. This victory added to the possessions of *Seleucus* all those provinces which had formerly been subject to *Lyfimachus*. The former exulted much in his good fortune; being chiefly pleased that he was now the last of *Alexander's* captains, and by this victory became, as he styled it, *the conqueror of conquerors*; and on this account he is generally called *Nicator*, or *the Conqueror*. His triumph, however, on this occasion, was but short-lived; for, seven months after, as he was marching towards *Macedon* to take possession of that kingdom, he was treacherously murdered by *Ptolemy Ceraunus*, on whom he had conferred innumerable favours. *Philetærus* prince of *Fergamus* purchased his body at a great price from *Ptolemy*, and sent it to his son *Antiochus*; who, with extraordinary pomp, burned it in *Seleucia* on the sea-coast, erecting on the place a magnificent chapel, which he called from his surname *Nicatorium*.

Seleucus
Calinicus.

Seleucus was succeeded by his son *Antiochus Soter*, who held the empire 19 years. He resigned to *Antigonos Gonatus* all pretensions to the crown of *Macedon*; and having engaged in a war with *Eumenes* king of *Pergamus*, he was defeated by him, and obliged to yield up part of his dominions. He died in 261 B. C. and was succeeded by his son *Antiochus Theos*; who having engaged in a war with *Ptolemy Philadelphus* king of *Egypt*, the *Parthians* and *Bactrians* took an opportunity to revolt, and could never afterwards be reduced. In 246 B. C. he was poisoned by his wife *Laodice*, whom he had divorced for *Berenice* daughter to *Ptolemy*, with whom he made peace on the revolt of the *Bactrians*. On the death of *Ptolemy*, *Antiochus* divorced *Berenice*, and took back *Laodice*; who, to secure herself against the effects of his fickle disposition, poisoned him, as we have just mentioned, and raised to the throne her own son, named *Seleucus Callinicus*. Not thinking herself safe, however, as long as *Berenice* lived, *Laodice* began immediately to concert measures for putting both her and her son to death. *Berenice* attempted to save herself by retiring to *Daphne*, where she shut herself up in an asylum built by *Seleucus Nicator*. There she was closely besieged by the sons of *Seleucus*; of which the cities of *Asia* having intelligence, formed a confederacy in her favour. Her brother the king of *Egypt* also hastened to her relief with a considerable army; but before either of these could come to her assistance, both she and her son were barbarously murdered, with all the *Egyptians* who attended them.

Ptolemy, on hearing the melancholy news of his

sister's death, determined to take the most severe vengeance on her murderers. Joining his forces to those of the *Asiatics*, he carried every thing before him. Having in the first place put an end to the life of *Laodice*, he made himself master of all *Syria* and *Cilicia*; then passing the *Euphrates*, he subdued all the country as far as *Babylon* and the *Tigris*; and had not the progress of his arms been interrupted by a sedition which obliged him to return to *Egypt*, it is more than probable that he would have subdued the whole *Syrian* empire. As soon as he was returned, *Seleucus* attempted to revenge himself; but his fleet being destroyed by a violent storm, and his land-army defeated by *Ptolemy*, he concluded a truce for ten years. During all this time the *Parthian* prince had established himself so firmly on the throne, that it was in vain to think of dispossessing him. However, as soon as his other affairs would permit, *Seleucus* undertook an expedition against *Araces* the *Parthian* monarch; by whom he was utterly defeated, taken prisoner, and carried into *Parthia*, where he died four years after. He was succeeded by his eldest son *Seleucus Ceraunus*, a weak prince, who was poisoned by a conspiracy of two of his officers, when he had reigned one year; after which his brother *Antiochus*, surnamed the *Great*, ascended the throne in 225 B. C.

In the very beginning of his reign, two of his generals, *Alexander* and *Molo*, rebelled against him. The former had been appointed governor of *Persia*, and the latter of *Media*; but they, despising the king's youth, refused to obey. The occasion of this revolt is said to have been their dread of the cruelty of *Hermias* the king's prime minister; and as they hoped to draw into their schemes *Achæus* governor of the provinces of *Asia Minor*, they doubted not of success. In this, however, they failed; but this did not discourage them from proceeding in their rebellion. *Epigènes*, the commander of the troops about the king's person, advised him to march without delay against the rebels; but as *Hermias* reproached him with treachery and a design to betray the king into the hands of his enemies, *Antiochus* sent two of his generals into the east, while he himself undertook an expedition against *Ptolemy Philadelphus*, with a view of recovering *Cælysia*. In this attempt, however, he was disappointed; and the generals whom he had sent into the east were totally defeated, and their troops cut off: upon which he determined to lay aside for the present his *Syrian* enterprise, and march in person against the rebels. This was again opposed by *Hermias*; but as he found it impossible to alter the king's mind, the treacherous minister found means to get *Epigènes* the author of this project executed, under pretence of holding a correspondence with *Molo* one of the rebel chiefs. *Antiochus* in the mean time pursued his march against the rebels, whom he defeated in a pitched battle; upon which their chiefs laid violent hands on themselves. On his return he received the submission of the *Atropati*, a barbarous people in *Media*; and put to death his prime minister *Hermias*, whom he found hatching treacherous designs against him. During his lifetime, however, the traitor, by accusing *Achæus* of treason, had obliged him to revolt in his own defence; so that the king had still two im-

important wars on his hands, viz. that with Ptolemy king of Egypt, and the other against Achæus. After some deliberation, he resolved to march first against the king of Egypt; and was at first very successful, reducing many cities in Cæleſyria and Palestine, and defeating the Egyptians in a pitched battle: but in the year 217 B. C. being worsted in the battle of Raphia, he was obliged to abandon all his conquests; of which Ptolemy immediately took possession, and Antiochus was obliged to cede them to him, that he might be at leisure to pursue the war against Achæus.

Antiochus having made vast preparations for his expedition, soon reduced Achæus to such distress, that he was obliged to shut himself up in the city of Sardis, which he defended for some time with great bravery; till at last, being betrayed by two Cretans, he was delivered up to the king, and by his order put to death. Antiochus then undertook an expedition against the Parthians, whom he obliged to conclude a peace on very advantageous terms. He then turned his arms against the king of Bactria, whom he also compelled to agree to his terms; one of which was, that he should give him up all his elephants. For the confirmation of the treaty, the king of Bactria sent his son to Antiochus; who being taken with his majestic mien and agreeable conversation, gave him one of his daughters in marriage. He then crossed Mount Caucasus, and entered India; where having renewed his alliance with the king of that country, he received also of his elephants, which increased his flock to 150. From India he marched into Arachosia, Drangiana, and Carmania, establishing order and discipline in those countries: then passing through Persia, Babylon, and Mesopotamia, he returned to Antioch, after an absence of seven years.

In the year 204 B. C. Antiochus entered into a league with Philip of Macedon, on purpose to deprive Ptolemy Epiphanes, the infant-king of Egypt, of all his dominions. The Egyptians, however, put the young king under the tuition of the Romans; who immediately required the confederate princes to desist from any enterprise against the king of Egypt, under the penalty of incurring the displeasure of the republic. After delivering this message, M. Emilius Lepidus, one of the ambassadors, repaired to Egypt, where he took upon himself the office of regent and guardian to the young king. Having regulated affairs there in the best manner he could, he returned to Rome, after having appointed one Aristomenes, an Acarnanian, to be chief minister to the king. Aristomenes being a man of prudence and fidelity, acquitted himself very well in his new station. Having taken care to recruit his army as well as he could, he sent one Scopas, a man of great authority among the Ætolians, into that country, to raise auxiliaries. Scopas soon raised an army of 6000 Ætolians, at that time reputed the best soldiers in the world; and having joined the Egyptian army, reduced all Judea, put a garrison into the castle at Jerusalem, and, on the approach of winter, returned to Alexandria loaded with booty. These exploits, however, were performed when Antiochus was absent in Asia Minor; and no sooner was he returned than the face of affairs was changed. Scopas was defeated in a pitched battle, where one half of his men were destroyed. He him-

self escaped to Sidon, where he shut himself up with 10,000 of his soldiers; but Antiochus having invested the place, Scopas was reduced to the necessity of surrendering at discretion. The king pursued his conquests; recovered all Palestine and Cæleſyria; after which he invaded Asia Minor, in hopes of reducing it also, and restoring the Syrian empire to the same extent it had in the time of Seleucus Nicator. The free cities in Asia Minor immediately had recourse to the Romans, who sent an embassy to Antiochus on the occasion; but as both parties put on those haughty and imperious airs to which they thought the greatness of their power gave them a right, no satisfaction was given, but every thing tended to an open rupture. While matters were in this situation, Hannibal the Great being obliged to leave his own country, fled to Antiochus; from whom he met with a gracious reception. As Hannibal had, while a child, sworn perpetual enmity with the Romans, he used all his eloquence to persuade Antiochus to make war with them; and as the many victories which he had gained over them left no room to doubt of his capacity, Antiochus doubted nothing of being able, by his assistance, to conquer that haughty people. Several embassies passed between the two nations; but chiefly with a design, on the part of Antiochus, to gain time. Hannibal endeavoured to draw his countrymen into the confederacy against Rome, but without effect. Antiochus having strengthened himself by several alliances, at last resolved to begin the war in earnest.

To consult on the measures proper to be taken, he called a council of war; but excluded from it the only man whose advice he ought to have followed; namely, Hannibal the Carthaginian. The reason of this was, that he had become jealous of him from the too great intimacy, as he thought, which he had kept with the Roman ambassadors. However, in this council it was agreed that the war should be immediately commenced. The king himself was prevailed upon by the Ætolians to pass over into Greece, and at the same time entirely to reject the advice which Hannibal had formerly given, of sending him with an army into Italy. Here he was made generalissimo of all the Greek forces; but made none of those efforts that had formerly obtained him the title of Great. Indeed it now plainly appeared, not only that he was incapable of carrying on war against such enemies as the Romans, but even of accepting proper advice when it was given him. In another council, into which Hannibal was admitted, that commander advised the king, before he undertook any thing else, to use his utmost endeavours to gain over Philip of Macedon; which, he said, was a step so important, that if it could be gained, they might, without much ado, become masters of all Greece. But if Philip could not be prevailed on to make war on the Romans, he was of opinion that the king should send his son Seleucus into Macedon at the head of an army, and thus prevent Philip from giving the Romans any assistance. But he still maintained, that the only way to defeat the Romans was to send an army into Italy. This advice was again rejected; and the king imprudently became the aggressor, by falling on a body of 500 Romans before war had been declared. He also made king Philip his enemy, by entertaining the regent of Atha-

Syria.

mania, who was a pretender to the crown of Macedonia. To complete all, he himself fell in love, tho' above 50 years of age, with a beautiful young woman of Chalcis, whom he married; and became to great a slave to this passion, that he entirely neglected his affairs; the army gave themselves up entirely to dissipation and debauchery, and every trace of military discipline evanished.

102
Is defeated by the Romans at Thermopylae.

In the year 191 B. C. Antiochus was raised from his lethargy by a declaration of war against him at Rome, and set out for Ætolia. His army at this time amounted to no more than 10,000 foot and 500 horse. He had been made to believe that he would receive a vast reinforcement in Ætolia: but when he came to make the experiment, he soon found his mistake; all the troops he could raise there amounted to no more than 4000 men. With this force, so exceedingly inadequate to the purpose, he was obliged to oppose the Roman army, who were advancing in conjunction with the Macedonians, and had already made surprising progress. Antiochus seized the Straits of Therinopylae; but was driven from them by the Romans, the king himself being the first that fled. Almost his whole army was destroyed in the battle or in the pursuit, and Antiochus returned with disgrace into Asia.

103
His fleet defeated by that of the Romans.

Soon after his return, Antiochus equipped a fleet of 200 sail; on which he immediately embarked for the Thracian Chersonesus, now Crim Tartary, where he fortified the cities of Lyfimachia, Sestus, and Abydos, with others in that neighbourhood, to prevent the Romans from crossing the Hellespont. In the mean time Polyxenas the Syrian admiral sent intelligence to the king that the Roman fleet had appeared off Delos; upon which he desired him to seek them out and engage them at all events. He did so, and was defeated with the loss of 40 ships taken or sunk in the engagement. This was soon after revenged by the destruction of the Rhodian fleet by the artifice of Polyxenas; but in the end the king's affairs went every where to wreck. Having laid siege to the city of Pergamus, he was obliged to raise it with loss; the Phœnician fleet commanded by Hannibal was defeated by the Rhodians; and soon after the Syrian fleet under Polyxenas was utterly defeated by the Romans. Antiochus was so much disheartened by these repeated defeats, that he appeared like one infatuated. Instead of fortifying more strongly those cities which lay on the frontiers of his kingdom, he entirely deserted them: and thus Lyfimachia and Abydos, the two keys to Asia, fell into the hands of the Romans without the least resistance.

104
Meets with two other defeats, and becomes like one infatuated.

The arrival of the Romans in Asia struck Antiochus with such terror, that he instantly sued for peace. The terms he offered were indeed very advantageous, but by no means agreeable to the expectations of the Romans. They therefore gave him this final answer: 1. That since he had drawn upon himself the war, he should defray the whole expence of it; 2. that he should restore liberty in general to all the Greek cities in Asia; and, 3. that to prevent future hostilities, he should relinquish all Asia on this side Mount Taurus. These terms, however, still appeared to him so intolerable, that he resolved to continue the war; and determined also to take the most imprudent me-

thod of carrying it on, namely, by hazarding all on the event of a general engagement. The king encamped near Magnesia, and strongly fortified his camp. The Romans insulted him in his trenches, and proposed to attack his fortifications if he continued to decline an engagement. At last the king, thinking it would be shameful for him longer to refuse an engagement, being at the head of an army far more numerous than that of the enemy, in a friend's country, and in the midst of his allies, resolved at all events to accept the challenge, and accordingly prepared for a decisive battle.

106
Battle of Magnesia.

The Roman army consisted of four legions, partly Romans and partly Latins, each legion at this time containing 5500 men, and of 7000 auxiliaries sent by the kings of Pergamus and Macedon; but of these 2000 were ordered to guard the camp during the action. The Romans were posted in the centre, and the Latins in the two wings, the left of which extended to the river. On the side of the right wing, to cover and support it, the consul posted the auxiliary troops of Eumenes, a small body of horse, and some Trallians and Cretans lightly armed. Sixteen elephants which the Romans had were placed behind the army by way of corps-de-reserve, the consul not thinking it proper to oppose them to those of the enemy, which were far more numerous, being in all 52, and besides excelled the Roman elephants in strength, height, and courage, the former being brought from India and the latter from Africa. As for the Syrian army, all the nations of the east seemed to be assembled to support the cause of Antiochus. But the main strength of it consisted in 16,000 foot, armed after the Macedonian manner, who composed the phalanx. This body faced every way, was armed with long pikes, and taught to fight in close order, as the soldiers of Alexander the Great had formerly been. Antiochus did not draw up his phalanx as usual, but divided it into 10 companies separated from each other, placing, in the spaces between each of the companies, an elephant loaded with a tower full of armed men. On the right of the phalanx was drawn up in a line part of the cavalry, viz. 1500 Asiatic Gauls, 3000 horse armed cap-a-pee, and 1000 more, the flower of the Median cavalry. At some distance from these followed the cavalry of the king's household richly clothed, and wearing bucklers plated over with silver. In the same line twelve hundred Scythians on horseback, armed with bows and arrows, made a great figure, being all chosen men, and of an extraordinary size. The light-armed troops, to the number of 3000, partly Trallians and partly Cretans, with 10,000 Myrian archers and 4000 men more, partly Cyrtæans armed with slings, partly Persians armed with bows, and partly Arabians mounted on dromedaries, closed the right wing, which was led on by the king in person, surrounded by a body of Syrians and Lydians well mounted, but not heavily armed. The left wing was commanded by Seleucus and Antipater; the former the king's son, and the latter his nephew, and disposed thus: Close to the phalanx were posted 1500 Galatians and 2000 Cappadocians, which king Ariarathes had sent to the assistance of his father-in-law. Next to these were placed 2700 auxiliaries sent from different countries; these

Syria.

these were followed by 3000 cuirassiers well mounted; and, lastly, in the flank of this wing marched 2000 horse lightly armed. At some distance were placed several small bodies of light-armed troops both foot and horse; among which were 2500 Galatian horse, some Tarentines, Cretans, Carians, Cilicians, &c. The phalanx, which was in the centre, was commanded by three officers of distinction, viz. Minio, Zeuxis, and Philip. A vast number of chariots, armed with hooks and scythes, were drawn up before the first line, as were likewise a great many elephants carrying towers with several floors, all filled with slingers and archers; besides many camels, animals then unknown to the Roman troops, mounted by Arabians armed with swords six feet long, that the riders might from their backs reach the enemy. The Romans had never seen a more numerous army, nor one more finely adorned; nevertheless they never showed so great a contempt for an army as for this which they were now going to attack.

On the day of the battle the weather proved very favourable to the Romans; for a thick fog rising in the morning, the day was almost turned into night, so that the Syrian commanders could not have all the corps under their command in view, on account of their great extent, nor send them proper orders in time; whereas the fog was not thick enough to prevent the Roman generals from seeing their several bodies at the greatest distance, as they took up but little ground. Besides, the damp which was occasioned by the fog slackened the strings of the enemy's bows, so that the Asiatics who used them could shoot their darts and arrows but faintly. The whole dependence of Antiochus in the first attack was on his armed chariots, which were to cut their way into the Roman army. For this purpose they had long halberds fastened to their poles, and sharp hooks to their axletrees; the former were about the height of a man's head, and the latter almost swept the ground, and cut off the legs of all who stood in their way. But Eumenes undertook to render them useless, and even fatal to the enemy. This brave prince, putting himself at the head of the bowmen and slingers, ordered them to charge, not in a body, but divided in platoons, and to aim only at the horses in the chariots. Accordingly, as soon as the chariots moved, Eumenes advanced at the head of his men, who pouring on them from every quarter, darts, stones, and javelins, and at the same time, shouting as loud as they could, so frightened the horses that they could no longer be kept in order, but, scouring up and down, and turning against their own troops, fell on the Arabians who supported them, which occasioned a great confusion in that quarter. Those in the Syrian army who were at a distance, hearing the noise and outcries, and not knowing the cause of them, were struck with no small terror. After this advantage, the Roman cavalry advanced, and fell on those whom the chariots had put in disorder. The Syrians being already intimidated, after a faint resistance, gave way; and the Romans made a great slaughter of their men and horses, both being borne down with the weight of their heavy armour. Eumenes charged the left wing, in which Seleucus commanded, with such vigour, that he put it to flight; and the fugitives flying to the phalanx for protection, put

Vol. X.

that body likewise in disorder: which Domitius observing, advanced against it at the head of his legions, but could not break it till he ordered his men to attack the elephants; which, as before observed, were placed in the spaces between the companies. The Romans had learnt, in their wars with Pyrrhus and Hannibal, not to fear those monsters which were once so terrible to them. They attacked them, therefore, with great resolution; and driving them against the phalangites, put that body into disorder, by means of those very animals which had been posted there for its defence.

But in the mean time advice was brought that the left-wing of the Romans was in great danger. Antiochus, who had observed that the flanks of the left-wing were quite open and uncovered, the four squadrons which covered it having joined the rest of the cavalry to fall upon the enemy's left-wing, had charged it at the head of all his auxiliaries, not only in front but in flank. The Roman infantry, seeing themselves in imminent danger of being surrounded and hemmed in on all sides, fled in great disorder to their camp, which was guarded by 2000 men under the command of a legionary tribune called *Emilius*. This man seeing the Romans flying towards him, marched out at the head of all his troops to meet them; and after having bitterly reproached them for their cowardice and ignominious flight, ordered his men to draw their swords, and cut in pieces such as should advance one step farther, or refuse to face about against the enemy. This order, given so seasonably, and put in execution without mercy against some, had the desired effect. Those who were flying first halted; and then, being both reinforced and encouraged by *Emilius*, returned under his conduct to wipe off the dishonour of their flight. At the same time *Antalus* the brother of *Eumenes*, having left the right-wing on his receiving advice that the left was in danger, arrived very seasonably with 200 horse. Antiochus observing that the troops which had fled were returning to the battle, and that the enemy's right-wing was ready to fall upon him, turned his horse about and fled. This served in a manner as a signal for the rest of the troops, for the whole Syrian army immediately turned their backs. Eumenes alone pursued them at the head of the cavalry, and made a most dreadful havoc of the fugitives. The Romans walking over heaps of dead bodies, especially where the phalanx stood, marched up to the Syrian camp, attacked, and plundered it. The riches they found in it are not to be defcribed: the taking of it cost the Romans a new battle, which proved more fatal to the Syrians than that in the field; for the Romans having, in spite of a most desperate resistance, forced the intrenchments, gave no quarter, but put all to the sword without distinction. There fell this day in the battle, in the pursuit, and in the plunder of the camp, 50,000 foot, and 4000 horse; 1500 were taken prisoners, and 15 elephants. In the consular army there were but 300 foot killed, and 25 horse. Eumenes had only 15 of his men killed; so that this victory, as we are told by the ancients, seemed a prodigy to all nations, both of the east and west.

Antiochus retired to Sardis with as many of his forces that had escaped the slaughter as he could draw

together. From Sardis he soon marched to rejoin his son Seleucus, who had fled to Apamea. As for the consul, he took advantage of the king's defeat and flight, making himself master of all the neighbouring countries. Deputies hastened to him from all parts; the cities of Thyatira, Magnesia, Trallis, Magnesia in Caria, all Lydia, and Ephesus itself, though highly favoured by Antiochus, declared for the Romans. Polyxenidas, upon the news of the king's defeat, left the port of Ephesus, and sailed to Patara, where he landed with a very small guard, and returned by land into Syria. The consul took the road to Sardis, which opened its gates to him. As he stopped there, his brother Africanus, as soon as his health allowed him, came and joined him in that city, and congratulated him on the glory he had so lately acquired.

Antiochus finding his affairs in a bad situation both by sea and land, and not daring to appear before the consular army in the field, sent Antipater his brother's son, and Zeuxis, who had been governor of Lydia and Phrygia, to sue for a peace. They were ordered to treat chiefly with the elder brother, of whose clemency and good-nature Antiochus entertained a high opinion. Accordingly, on their arrival at Sardis, where the consul then was with his brother, they addressed the latter, and were by him presented to the consul. Their speech was very submissive, and such as became a vanquished people.

Hereupon a council was summoned, and after long debates the ambassadors were called in; and Scipio Africanus being desired by the consul to acquaint the deputies with the resolutions of the assembly, is said to have expressed himself in the following terms: "We are sensible that the victory which we have lately gained is owing to the gods, and therefore shall treat the vanquished with moderation, demanding little more of them now than we did at our first entering into Asia.

110
Antiochus obtains peace on very hard terms.

Antiochus shall obtain a peace upon the following terms: That he give up his pretensions to Europe, confine his dominions to Asia beyond mount Taurus: and that he pay 15,000 Euboic talents for the expences of the war; 500 down, 2500 when the senate and people shall confirm the articles, and 1000 more every year for 12 years together. We also insist upon his satisfying king Eumenes, and his paying him the 400 talents he owes him, and what remains due for the corn which his father sent to the king of Syria. It is likewise the pleasure of the council that you deliver up to us Hannibal the Carthaginian, Thoas the Ætolian, Mnesiochus the Acarnanian, and Philo and Eubulus two Chalcidians; for these have been the authors of our divisions, the incendiaries who kindled the present war. Lastly, the king of Syria, for a further proof of his sincerity, shall give us 20 such hostages as we shall choose, of whom Antiochus his youngest son shall be one."

The ambassadors of Antiochus had been ordered to refuse no terms; and therefore these were accepted, and the whole affair concluded. So that the Syrian ambassadors now prepared to set out for Rome, to get the conditions of peace proposed by Scipio ratified there. In the mean time, the consul dividing his army into three bodies, put it into winter-quarters; one part continued at Magnesia, another was sent to Trallis, and the third to Ephesus, where the Scipios took

up their quarters. There they received a new embassy from Antiochus, with the hostages he had promised, the Roman prisoners and deserters, and the strangers which the consul had demanded, except Hannibal, who after the king's defeat had fled out of his dominions; and Thoas the Ætolian, who, as soon as he heard that a treaty was on foot between Antiochus and the Romans, had returned to Ætolia, where a war was likely to break out between that republic and Rome. L. Aurelius Cotta was sent with the ambassadors to Rome, to acquaint the senate with the particulars of the treaty. When they appeared before the conscript fathers, they spoke with great submission, and only desired them to ratify the articles which the Scipios had offered to their master. The senate, after examining them, ordered that a treaty of peace should be concluded with Antiochus, and the articles of it engraved on brass, and fixed up in the capitol. They only added one clause, which was, That the Syrians should change every year all their hostages, except the son of king Antiochus, who should continue at Rome as long as the republic thought fit. The peace being thus ratified, and all Asia on this side mount Taurus delivered into the hands of the Romans, the Greek cities were by them restored to their liberty, the provinces of Caria and Lydia given to the Rhodians, and all the rest that had belonged to Antiochus bestowed upon Eumenes.

Antiochus did not long survive his misfortune at his death. Magnesia. Some tell us, that being greatly puzzled how to raise the sum he had engaged to pay to the Romans, he seized on the riches which had for many ages been deposited in a temple of Jupiter Belus in the province of Elymais; upon which the populace rose in arms, and slew him and all his attendants. Others inform us, that he was killed at an entertainment by one of his guests.

Antiochus the Great died in 187, and with him the glory of the Syrian empire. The Romans now gave laws to the kings of Syria, inasmuch, that when Antiochus Epiphanes the grandson of Antiochus the Great hesitated at obeying the commands of the senate, one of the ambassadors drew a circle round him with a rod on the floor, and told him, that he should not go out of that spot before he had told him what he was to do. The most remarkable transactions of this prince are his wars with the Jews, and persecutions of them; of which a full account is given under the article Jews. After a variety of usurpers and tyrants, the kingdom of Syria fell under Tigranes king of Armenia in the year 83 B. C.; and upon his overthrow by the Romans, it became a province of the dominions of the republic. From them it was taken by the Saracens in the reign of the caliph Omar, and is now a province of Turkey in Asia.

Syria, in general, is blessed with a serene, temperate, and healthful air; being refreshed, during the hot sultry months of June, July, and August, by cool breezes from the Mediterranean. The face of the country is mostly level and delightful, and the soil naturally deep, rich, and fertile; so that it would produce in the greatest plenty, if cultivated, whatever could be wished for, either for the sustenance, pleasure, or convenience of the inhabitants; but, like all the other countries possessed by the Turks, a great part of

113
Climate, soil, &c. of the country.

Syria
||
Syltem.

it lies waste and uncultivated. With the little culture bestowed upon it, it produces, in many places, abundance of corn, wine, oil, figs, lemons, oranges, melons, canes, dates, and cotton, with aromatic and medicinal herbs. In Syria also are bred great numbers of buffaloes and other oxen, camels, dromedaries, wild-boars, deer of all sorts, hares, rabbits, and other game; with a kind of goats whose hair is long and of a beautiful colour; and a breed of sheep, whose wool is very fine, and their tails so large that they sometimes weigh 30 pounds.

SYREN. See SIREN.

SYRINGA, LILAC, in botany, a genus of the monogynia order, belonging to the diandria class of plants. There are two species; both of them deciduous flowering shrubs, adorned with oval, heart-shaped, and spear-shaped simple leaves, and large bunches of odoriferous small funnel-shaped flowers, white, blue, and purple, in the different varieties. They are all hardy plants; and though natives of Persia, will bear the severest winters. They are easily propagated, by seed, suckers, or layers.

SYRINGE, a well-known instrument, serving to imbibe or force in a quantity of fluid, and to squirt or expel the same with violence. The word is formed from the Greek *συνεζ*, or the Latin *syrix*, "a pipe."

—A syringe is only a single pump, and the water ascends in it on the same principle as in the common sucking pump. See HYDROSTATICS, n° 23, *et seq.*

SYRUP, in pharmacy, a saturated solution of sugar, made in vegetable decoctions or infusions. See PHARMACY, n° 480—500.

SYSTEM, in general, denotes an assemblage or

chain of principles and conclusions, or the whole of any doctrine, the several parts whereof are bound together, and follow or depend on each other; in which sense we say a *system of philosophy*, a *system of divinity*, &c.—The word is formed from the Greek *συστημα*, "composition, compages."

SYSTEM, in the animal œconomy, the *vascular*, the *nervous*, and the *cellular*. See ANATOMY.

SYSTEM, in music, an assemblage of the rules for harmony deduced from some common principle by which they are re-united; by which their connection one with another is formed; from whence, as from their genuine source, they natively flow; and to which, if we would account for them, we must have recourse. See the articles CHROMATIC, DIATONIC, ENHARMONIC, HARMONY, INTERVAL, and MUSIC.

SYSTEM, in botany. See BOTANY, Sect. ii. iii. iv.

SYSTEM, in astronomy. See ASTRONOMY, sect. iv.

SYSTOLE, in anatomy, the contraction of the heart, whereby the blood is drawn off its ventricles into the arteries; the opposite state to which is called the *diastole*, or *dilatation*, of the heart. See ANATOMY, n° 388.

SYSTYLE, in architecture, that manner of placing columns where the space between the two shafts consists of two diameters or four modules.

SYZYGY, SYZYGIA, in astronomy, a term equally used for the conjunction and opposition of a planet with the sun.—The word is formed from the Greek, *συσυγία*, which properly signifies "conjunction." On the phenomena and circumstances of the syzygies a great part of the lunar theory depends. See ASTRONOMY, n° 220.

T.

T, or t, the 19th letter and 15th consonant of our alphabet, the sound whereof is formed by a strong expulsion of the breath through the mouth, upon a sudden drawing back of the tongue from the fore-part of the palate, with the lips at the same time open. The proper sound of this letter is that in *tan*, *ten*, *tin*, *tun*, *fat*, *pot*, *put*, &c. When it comes before *i*, followed by a vowel, it is sounded like *s*, as in *nation*, *potion*, &c. When *h* comes after it, it has a two-fold sound; one clear and acute, as in *thin*, *thief*, &c.; the other more obtuse and obscure, as in *then*, *there*, &c.

In abbreviations, amongst the Roman writers, T. stands for *Titus*, *Titius*, &c.; Tab. for *Tabularius*; Tab. P. H. C. *Tabularius Provinciae Hispanie Citerioris*; Tar. *Tarquinius*; Ti. *Tiberius*; Ti. F. *Tiberii filius*; Ti. L. *Tiberii libertus*; Ti. N. *Tiberii Nepos*; T. J. A. V. P. V. D. *tempore judicem arbitrumve posulat ad del*; T. M. P. *terminum posuit*; T. M. D. D. *terminum dedicavit*; Tr. *trans*, *tribunus*; Tr. M. or Mil. *tribunus militum*; TR. PL. DES. *tribunus plebis designatus*; TR. AER. *tribunus aerarii*; TRV.

CAP. *triumviri capitales*; T. P. or TRIB. POT. *tribunicia potestate*; Tul. H. *Tullus Hostilius*.

Amongst the ancients, T. as a numeral, stood for *one hundred and sixty*; and with a dash at top, thus T, it signified *one hundred and sixty thousand*. In music, T stands for *tutti*, "all, or altogether."

TABANUS, the BREEZE-FLY; a genus of insects belonging to the order of diptera. The most remarkable species is the *bovinus*. The head of this insect is grey; the eyes almost of a black brown, occupying the greatest part of it. The thorax is of a grey colour; the abdomen is yellowish, with a triangular white spot on the middle of every ring, which constitutes a longitudinal band of spots, the point of which is directed towards the thorax. The thighs are blackish, and the legs yellow. The wings are somewhat dusky, with brown veins of a deeper dye. This insect is the terror of horned cattle, horses, &c. Its mouth is armed with two sharp hooks which penetrate their hide; while with its proboscis, which is shaped like a ring, it sucks their blood, of which it is very fond. The puncture of the tabanus is keen and painful. The

System
||
Syzygy.

insect is very common in damp woods and meadows, especially during the great heats, when it is most troublesome. The horned cattle are sometimes so molested by their stings, that they go mad, run down precipices, tear themselves on the stumps of trees, stones, &c.

TABBY, in commerce, a kind of rich silk which has undergone the operation of tabbying.

TABBYING, the passing a silk or stuff under a calender the rolls of which are made of iron or copper variously engraven, which bearing unequally on the stuff renders the surface thereof unequal, so as to reflect the rays of light differently, making the representation of waves thereon.

TABELLIO, in the Roman law, an officer or scrivener, much the same with our notaries-public, who are often called *tabelliones*.

TABERNACLE, among the Hebrews, a kind of building, in the form of a tent, set up, by express command of God, for the performance of religious worship, sacrifices, &c. during the journeying of the Israelites in the wilderness: and, after their settlement in the land of Canaan, made use of for the same purpose till the building of the temple of Jerusalem. It was divided into two parts; the one covered, and properly called the *tabernacle*; and the other open, called the *court*. The curtains which covered the tabernacle were made of linen, of several colours, embroidered. There were ten curtains, twenty-eight cubits long and four in breadth. Five curtains fastened together made up two coverings, which covered all the tabernacle. Over these there were two other coverings; the one of goat-hair, and the other of sheep-skins. The holy of holies was parted from the rest of the tabernacle by a curtain made fast to four pillars, standing ten cubits from the end. The length of the whole tabernacle was thirty-two cubits, that is, about fifty feet; and the breadth twelve cubits, or nineteen feet. The court was a spot of ground one hundred cubits long, and fifty in breadth, enclosed by twenty columns, each twenty cubits high and ten in breadth, covered with silver, and standing on copper bases, five cubits distant from one another; between which, there were curtains drawn, and fastened with hooks. At the east end was an entrance, twenty cubits wide, covered with a curtain hanging loose.

Feast of TABERNACLES, a solemn festival of the Hebrews, observed after harvest, on the fifteenth day of the month Tisri, instituted to commemorate the goodness of God, who protected the Israelites in the wilderness, and made them dwell in booths, when they came out of Egypt. On the first day of the feast, they began to erect booths of the boughs of trees, and in these they were obliged to continue seven days. The booths were placed in the open air, and were not to be covered with cloths, nor made too close by the thickness of the boughs; but so loose that the sun and the stars might be seen, and the rain descend through them. For further particulars as to the celebration of this festival, see *Levit. ch. xxiii.*

TABERNÆ, (anc. geog.) See *TRES TABERNÆ*.

TABLE, a moveable piece of furniture, usually made of wood or stone, and supported on pillars or the like, for the commodious reception of things placed thereon.

TABLE is also used for the fare or entertainment served up.

TABLE, in mathematics, systems of numbers calculated to be ready at hand for the expediting astronomical, geometrical, and other operations.

Astronomical TABLES, are computations of the motions, places, and other phenomena of the planets, both primary and secondary. See *ASTRONOMY*.

TABLE-Mountain, a mountain of Africa, being the most westerly cape or promontory in that part of the world, and near the Cape of Good Hope. The bay which is formed thereby is called the *Table bay*.

Laws of the Twelve TABLES, were the first set of laws of the Romans: thus called either by reason the Romans then wrote with a style on thin wooden tablets covered with wax; or rather, because they were engraven on tables or plates of copper, to be exposed in the most noted part of the public forum. After the expulsion of the kings, as the Romans were then without any fixed or certain system of law, at least had none ample enough to take in the various cases that might fall between particular persons, it was resolved to adopt the best and wisest laws of the Greeks. One Hermodorus was first appointed to translate them, and the decemviri afterwards compiled and reduced them into ten tables. After a world of care and application, they were at length enacted and confirmed by the senate and an assembly of the people, in the year of Rome 303. The following year they found something wanting therein, which they supplied from the laws of the former kings of Rome, and from certain customs which long use had authorized: all these being engraven on two other tables made the law of the twelve tables, so famous in the Roman jurisprudence, the source and foundation of the civil or Roman law.

TABLES of the Law, in Jewish antiquity, two tables on which were written the decalogue, or ten commandments, given by God to Moses on Mount Sinai.

TABOR (MOUNT). See *THABOR*.

TACAMAHACA, in pharmacy, a solid resin, improperly called a *gum* in the shops. It exsudes from a species of poplar; and is in repute for mitigating pain and aches, and as a vulnerary.

TACITUS (Caius Cornelius), a celebrated Roman historian, and one of the greatest men of his time, was raised for his merit to the first posts in the empire. Vespasian and Titus gave him considerable employments; he became prætor under Domitian, and two years after was made consul in the room of Virginus Rufus in the year 97. But these dignities gave him but a small share of glory, compared with that he obtained by the labour of his pen. There are still extant, 1. Five books of his history. 2. His Annals. 3. A Treatise on the different nations which in his time inhabited Germany: and, 4. The Life of Agricola his father-in-law. There is also attributed to him a Treatise on Eloquence, which is more generally allowed to have been written by Quintilian. Tacitus's other works are lost. Pliny the Younger, who was his friend, and the learned since his time, give the works of Tacitus the highest praises.

TACK, a rope used to confine the foremost lower-corners of the courses and stay-sails in a fixed position, when

Tack.

when the wind crosses the ship's course obliquely. The same name is also given to the rope employed to pull out the lower corner of a fludding-fail or driver to the extremity of its boom.

The main-fail and fore-fail of a ship are furnished with a tack on each side, which is formed of a thick rope tapering to the end, and having a knot wrought upon the largest end, by which it is firmly retained in the clue of the fail. By this means one tack is always fastened to windward, at the same time that the fleet extends the fail to the leeward. See *CHESTREE*.

TACK, is also applied, by analogy, to that part of any sail to which the tack is usually fastened.

A ship is said to be on the starboard or larboard tack, when she is close-hauled, with the wind upon the starboard or larboard side: and in this sense the distance which she sails in that position is considered as the length of the tack; although this is more frequently called *board*. See that article.

To *TACK*, to change the course from one board to another, or turn the ship about from the starboard to the larboard tack, in a contrary wind. Thus the ship *A*, being close-hauled on the larboard tack, and turning her prow suddenly to windward, receives the impression of the wind on her head-fails *a*, by which the sails off upon the line of the starboard-tack *a*. Tacking is also used in a more enlarged sense, to imply that manœuvre in navigation by which a ship makes an oblique progression to the windward, in a zigzag direction. This, however, is more usually called *heaving*, or *turning to windward*.

Thus, suppose the ship *A* bound to a port *B* lying to windward, with the wind northerly, as expressed by the arrow. The fails *a*, *b*, *c*, being braced obliquely with the keel, the wind also falls upon their surfaces in an oblique direction, by which the ship is pushed to leeward, as explained in the article *LEE-way*. Hence, although the apparently fails *W*. *N*. *W*. upon the larboard-tack, as expressed in the dotted line *Ad*, and *E*. *N*. *E*. upon the other *df*, yet if the lee-way is only one point, (and indeed it is seldom less in the smoothest water), the course will accordingly be *W*. by *N*. upon one tack, and *E*. by *N*. upon the other, as represented by the lines *Ae*, and *eg*.

If the port *A* were directly to windward of the ship, it is evident that both tacks ought to be of equal length; or, in other words, that the ought to run the same distance upon each tack: but as the place of her destination lies obliquely to windward, she must run a greater distance upon one tack than the other; because the extremities of both boards should be equally distant from the line of her true course *BA*; so the larboard tack *Ae*, crossing the course more obliquely than the other *eg*, will necessarily be much longer.

As the true course, or the direct distance from *B* to *A* is only 12 leagues, it is evident that with a favourable wind she could reach it in a few hours. On the contrary, her distance is considerably increased by the length of her boards, in a contrary wind; which, by its obliquity with her sails, operates also to retard her velocity. Thus her first board *Ae*, on a *W*. by *N*. course, is equal to 5.7 leagues. The second tack *eg* is 9.2 leagues *E* by *N*. the third tack, parallel to *Ae*, is 11.5: the fourth, parallel to *eg*,

is 9.2: and the fifth, parallel to the first, 11.7 leagues. Finally, the sixth board is 4.8 leagues parallel to the second, which brings her to the port *B*. By this scheme it appears that she has run more than four times the extent of the line *AB*, her primitive distance; and this is the most favourable circumstances of a contrary wind, viz. when the sea is smooth, and when she may carry her full topails. For if the wind blows stronger, to render it necessary to reef the topails, she will soon make two points of lee-way, and accordingly run east on one board and west on the other. In this situation she will neither approach nor recede from the place of her destination: but if the wind increases, the sea will also be enlarged; a circumstance that still farther augments the lee-way. Hence the vessel will gradually fall off from the port, in proportion to the augmentation of the wind and sea, which occasions a proportional increase of lee-way.

In order to explain the theory of tacking a ship, it may be necessary to premise a known axiom in natural philosophy, That every body will persevere in a state of rest, or of moving uniformly in a right line, unless it be compelled to change its state by forces impressed; and that the change of motion is proportional to the moving force impressed, and is made according to the right line in which that force is exerted.

By this principle it is easy to conceive how a ship is compelled to turn into any direction, by the force of the wind acting upon her sails in horizontal lines. For the sails may be so arranged as to receive the current of air either directly or more or less obliquely. Hence the motion communicated to the sails must of necessity conspire with that of the wind upon their surfaces. To make the ship tack or turn round with her head to the windward, it is therefore necessary, after she has received the first impression from the helm, that the head-fails should be so disposed as to diminish the effort of the wind in the first instant of her motion; and that the whole force of the wind should be exerted on the after-fails; which, operating on the ship's stern, carries it round like a weathercock. But since the action of the after-fails to turn the ship will unavoidably cease when her head points to the windward, it then becomes necessary to use the head-fails, to prevent her from falling-off and returning to her former situation. These are accordingly laid aback on the lee-side, to push the vessel's fore part towards the opposite side, till the has fallen into the line of her course thereon, and fixed her sails to conform with that situation.

It has been observed above, that the first effort to turn the ship in tacking is communicated by the helm, which is then put to the lee-side. This circumstance being announced by the pilot or commanding officer, who then calls out *Helm's a-lee!* the head-fails are immediately made to shiver in the wind, by casting loose their sheets or bowlines. The pilot then calls, *Up tacks and sheets!* which is executed by loosening all the ropes which confine the corners of the lower sails, in order that they may be more readily shifted to the other side. When the ship has turned her head directly to windward, as in *d*, the pilot gives the order to turn about the fails on the main and mizen masts, by the exclamation, *Haul main-fail, haul!* the bowlines.

Tack.

Tack
||
Tania.

bowlines and braces are then instantly cast off on one side, and as expeditiously drawn in on the other side, so as to wheel the yards about their masts. The lower corner of the main-sail is, by means of its tack, pulled down to its station at the clewree; and all the after-sails are at the same time adjusted to stand upon the other board. Finally, when the ship has fallen off five or six points, the pilot cries, *Haul off all!* or, *Let go, and haul!* then the sails on the fore-mast are wheeled about by their braces; and as the ship has then a tendency to fall off, she is checked by the effort of the helm; which for that purpose is put hard a-lee. The fore-tack, or the lower corner of the fore-sail, being fixed in its place, the bowlines are hauled; and the other sails, which have been neglected in the hurry of tacking, are properly arranged to the wind; which exercise is called *trimming the sails*. See *LEE-WAY*, and *SAILING*.

TACK, in Scots law. See *LAW*, N° clxvii. 8—15.

TACKLE, among seamen, denotes all the ropes or cordage of a ship used in managing the sails, &c.

TACTICS, in the art of war, is the method of disposing forces to the best advantage in order of battle, and of performing the several military motions and evolutions.

TADCASTER, a town in the West Riding of Yorkshire, noted for the great plenty of limestone dug up near it. *W. Long.* v. 5. *N. Lat.* 53. 52.

TADPOLE, a young frog before it has disengaged itself from the membranes that envelope it in its first stage of life.

TENIA, in zoology; a genus of insects, belonging to the order of vermes zoophyta. The body is of an oblong form; and composed of evident joints or articulations, in the manner of the links of a chain, with a mouth and viscera in each joint. See *PLATE* cclxxxii.

1. The lata, long tape-worm, or solitary worm, infests the intestines of man and some other classes of animals, and seems to derive its nourishment from the chyle that is prepared in the stomach.—This worm is long and flat, composed of many very short rings that are articulated to each other, and has a kind of vein running through its whole length, which is more or less apparent.—This has occasioned the Germans to give it the name of *flat spinous worm*. It is not always of the same complexion; sometimes it appears of a blueish or reddish, and sometimes simply of a white colour; now and then it manifests itself only by a spot, which is to be perceived in the middle of each ring. In some of these worms this spot is of a blackish colour, in others of a colour more tending to white; and it rises into a very small prominence on each side, that is not easily apparent, however, to the naked eye. The tail or posterior end has never been capable of examination hitherto, because the worm breaks, and the patients void portions of it occasionally, either naturally or by the means of various remedies. Its body, which is usually several ells in length, and flattened like a ribbon, becomes gradually narrow towards its upper extremity, and at length terminates in a small thread-like appearance, of a foot or more in length. The point, which to the naked eye appears very minute, when examined by the lens, seems somewhat bulbous; and when viewed through a microscope that magnifies

Simmons's
Account of
the Tenia.

powerfully, is found to be the head of the worm, and is terminated by four horns of unequal length, which are perhaps the channels through which the animal derives its nourishment. The body of the worm extends itself throughout the whole intestinal canal, and often reaches even to the anus. It has been named *solitary worm*, because there commonly exists only one in the same subject: sometimes, however, two of them are found together; and sometimes, after the expulsion of the first, there regenerates a second. It is by no means easy to remove this worm: the purgative vermifuge remedies commonly used in phycic bring away portions of it, which we are always obliged to break, in order to separate them from those which remain behind; it seldom happens that they effect a complete cure.

2. The solium, or gourd-worm, resembles the former in many particulars, and is equally met with in the intestines of animals. It will be distinguished from the preceding one, by having neither the appearance of a head nor of a longitudinal vein: its rings are much longer than those of the solitary worm, and are striated through their whole length, being furnished only with a little lateral prominence. These rings are easily detached from each other, so that they appear as so many distinct worms, which have each of them life and motion independent as it were of the rest. The form of these rings, when viewed together, varies considerably. Those of the upper extremity are much more complete, short, narrow, and thin, than those lower down; the rings gradually becoming longer as they approach the lower end. These rings are in shape not unlike the seeds of gourd, and hence the name *gourd-worm*. Like the other, it is several ells in length, and is never voided whole, but by detached portions which fall off themselves.

For the methods of destroying and expelling these worms, see *MEDICINE*, n° 493.

TAFFETY, in commerce, a fine smooth silken stuff, remarkably glossy. See *SILK*. There are tafeties of all colours, some plain, and others striped with gold, silver, &c. others chequered, others flowered, &c. according to the fancy of the workmen.

TAGUS, the largest river of Spain; which, taking its rise on the confines of Arragon, runs south-west through the provinces of New Castile and Extremadura; and passing by the cities of Aranjuez, Toledo, and Alcantara, and then crossing Portugal, forms the harbour of Lisbon, at which city it is about three miles over; and about eight or ten miles below this it falls into the Atlantic ocean.

TAHEITEE. See *O-TAHEITEE*.

TAJACU, or PECCARY, in zoology, a species of hog. See *SUS*.

TAIL, the train of a beast, bird, or fish; which in land-animals serves to drive away flies, &c. and in birds and fishes to direct their course, and assist them in ascending or descending in the air or water.

TAIL, or *Fee-tail*, in law, is a conditional estate or fee, opposed to *fee-simple*. See *SEE*.

A conditional fee, at the common law, was a fee restrained to some particular heirs exclusive of others: as to the heirs of a man's body, by which only his lineal descendants were admitted, in exclusion of collateral heirs; or to the heirs-male of his body,

TENIA Solium.

A. B. *of Bell's*

1872

My dear Sir,
I have the honor to acknowledge the receipt of your letter of the 14th inst. in relation to the above named matter. I am sorry to hear that you are not satisfied with the result of the investigation. I have, however, no objection to your making such use of the facts as you may think proper. I am, Sir, very respectfully,
Yours truly,
J. H. [Name]

10-10-1872

Very respectfully,
J. H. [Name]

body, in exclusion both of collaterals and lineal females also. It was called a *conditional fee*, by reason of the condition expressed or implied in the donation of it, that if the donee died without such particular heirs, the land should revert to the donor. For this was a condition annexed by law to all grants whatsoever, that on failure of the heirs specified in the grant, the grant should be at an end, and the land return to its ancient proprietor. Such conditional fees were strictly agreeable to the nature of feuds, when they first ceased to be mere estates for life, and were not yet arrived to be absolute estates in fee-simple.

With regard to the condition annexed to these fees by the common law, it was held, that such a gift (to a man and the heirs of his body) was a gift upon condition that it should revert to the donor if the donee had no heirs of his body; but if he had, it should then remain to the donee. They therefore called it a *fee-simple* on condition that he had issue. Now we must observe, that when any condition is performed, it is thenceforth entirely gone; and the thing to which it was before annexed becomes absolute and wholly unconditional. So that as soon as the grantee had any issue born, his estate was supposed to become absolute by the performance of the condition; at least for these three purposes: 1. To enable the tenant to alienate the land, and thereby to bar not only his own issue, but also the donor, of his interest in the reversion. 2. To subject him to forfeit it for treason: which he could not do till issue born longer than for his own life, lest thereby the inheritance of the issue and reversion of the donor might have been defeated. 3. To empower him to charge the land with rents, commons, and certain other encumbrances, so as to bind his issue. And this was thought the more reasonable, because, by the birth of issue, the possibility of the donor's reversion was rendered more distant and precarious: and his interest seems to have been the only one which the law, as it then stood, was solicitous to protect; without much regard to the right of succession intended to be vested in the issue. However, if the tenant did not in fact alienate the land, the course of descent was not altered by this performance of the condition: for if the issue had afterwards died, and then the tenant or original grantee had died, without making any alienation, the land, by the terms of the donation, could descend to none but the heirs of his body; and therefore, in default of them, must have reverted to the donor. For which reason, in order to subject the lands to the ordinary course of descent, the donees of these conditional fee-simples took care to alienate as soon as they had performed the condition by having issue; and afterwards repurchased the lands, which gave them a fee-simple absolute, that would descend to the heirs general, according to the course of the common law. And thus stood the old law with regard to conditional fees: which things, says Sir Edward Coke, though they seem ancient, are yet necessary to be known, as well for the declaring how the common law stood in such cases, as for the sake of annuities, and such-like inheritances, as are not within the statutes of entail, and therefore remain as the common law. The inconveniences which attended these limited and fettered inheritances were probably

what induced the judges to give way to this subtle finess (for such it undoubtedly was), in order to shorten the duration of these conditional estates. But, on the other hand, the nobility, who were willing to perpetuate their possessions in their own families, to put a stop to this practice, procured the statute of Westminster the second (commonly called the statute *de donis conditionalibus*) to be made; which paid a greater regard to the private will and intentions of the donor, than to the propriety of such intentions, or any public considerations whatsoever. This statute revived in some sort the ancient feudal restraints which were originally laid on alienations, by enacting, that from thenceforth the will of the donor be observed; and that the tenements so given (to a man and the heirs of his body) should at all events go to the issue, if there were any; or if none, should revert to the donor.

Upon the construction of this act of parliament, the judges determined that the donee had no longer a conditional fee-simple, which became absolute and at his own disposal the instant any issue was born; but they divided the estate into two parts, leaving in the donee a new kind of particular estate, which they denominated a *fee-tail*; and vesting in the donor the ultimate fee-simple of the land, expectant on the failure of issue; which expectant estate is what we now call a *reversion*. And hence it is that Littleton tells us, that tenant in fee-tail is by virtue of the statute of Westminster the second. The expression *fee-tail*, or *feodum talliatum*, was borrowed from the feudists (See Crag. *l. s. t. 10. § 24, 25.*) among whom it signified any mutilated or truncated inheritance, from which the heirs-general were cut off; being derived from the barbarous verb *taliare*, to cut; from which the French *tailler* and the Italian *tagliare* are formed, (Spelm. *Gloss.* 531.)

Having thus shown the original of estates-tail, we now proceed to consider what things may or may not be entailed under the statute *de donis*. Tenements is the only word used in the statute: and this Sir Edward Coke expounds to comprehend all corporeal hereditaments whatsoever; and also all incorporeal hereditaments which favour of the realty, that is, which issue out of corporeal ones, or which concern or are annexed to or may be exercised within the same; as rents, estates, commons, and the like. Also offices and dignities, which concern lands, or have relation to fixed and certain places, may be entailed. But mere personal chattels, which favour not at all of the realty, cannot be entailed. Neither can an office, which merely relates to such personal chattels; nor an annuity, which charges only the person, and not the lands of the grantor. But in these last, if granted to a man and the heirs of his body, the grantee hath still a fee conditional at common law as before the statute, and by his alienation may bar the heir or reversioner. An estate to a man and his heirs for another's life cannot be entailed; for this is strictly no estate of inheritance, and therefore not within the statute *de donis*. Neither can a copyhold estate be entailed by virtue of the statute; for that would tend to encroach upon and restrain the will of the lord: but, by the special custom of the manor, a copyhold may be limited to the heirs of the body;

body; for here the custom ascertains and interprets the lord's will.

As to the several species of estates-tail, and how they are respectively created; they are either general or special. Tail-general is where lands and tenements are given to one, and the heirs of his body begotten: which is called *tail-general*; because, how often soever such donee in tail be married, his issue in general, by all and every such marriage, is, in successive order, capable of inheriting the estate-tail *per formam doni*. Tenant in *tail-special* is where the gift is restrained to certain heirs of the donee's body, and does not go to all of them in general. And this may happen several ways. We shall instance in only one; as where lands and tenements are given to a man and the heirs of his body, on Mary his now wife to be begotten. Here no issue can inherit but such special issue as is engendered between them two; not such as the husband may have by another wife; and therefore it is called *special tail*. And here we may observe, that the words of inheritance (to him and his heirs) give him an estate in fee; but they being heirs to be by him begotten, this makes it a fee-tail; and the person being also limited, on whom such heirs shall be begotten (*viz.* Mary his present wife), this makes it a fee-tail special.

Estates in general and special tail are farther diversified by the distinction of sexes in such entails; for both of them may either be in tail male or tail female. As if lands be given to a man, and his heirs-male of his body begotten, this is an estate in tail male general; but if to a man, and the heirs-female of his body on his present wife begotten, this is an estate in tail female special. And in case of an entail male, the heirs-female shall never inherit, nor any derived from them; nor, *e converso*, the heirs-male in case of a gift in tail female. Thus, if the donee in tail male hath a daughter, who dies leaving a son, such grandson in this case cannot inherit the estate-tail; for he cannot deduce his descent wholly by heirs-male. And as the heir-male must convey his descent wholly by males, so must the heir-female wholly by females. And therefore if a man hath two estates-tail, the one in tail male the other in tail female, and he hath issue a daughter, which daughter hath issue a son; this grandson can succeed to neither of the estates, for he cannot convey his descent wholly either in the male or female line.

As the word *heirs* is necessary to create a fee, so, in farther imitation of the strictness of the feudal donation, the word *body*, or some other words of procreation, are necessary to make it a fee-tail, and ascertain to what heirs in particular the fee is limited. If, therefore, either the words of inheritance or words of procreation be omitted, albeit the others are inserted in the grant, this will not make an estate tail. As if the grant be to a man and the issue of his body, to a man and his seed, to a man and his children or offspring; all these are only estates for life, there wanting the words of inheritance, "his heirs." So, on the other hand, a gift to a man, and his heirs male or female, is an estate in fee-simple and not in fee-tail; for there are no words to ascertain the body out of which they shall issue. Indeed, in last wills and testaments, wherein greater indulgence is allowed, an

estate-tail may be created by a devise to a man and his seed, or to a man and his heirs-male, or by other irregular modes of expression.

There is still another species of entailed estates, now indeed grown out of use, yet still capable of subsisting in law; which are estates in *libero maritagio*, or FRANKMARRIAGE. See that article.

The incidents to a tenancy in tail, under the statute Westminster 2. are chiefly these: 1. That a tenant in tail may commit waste on the estate tail, by selling timber, pulling down houses, or the like, without being impeached or called to account for the same. 2. That the wife of the tenant in tail shall have her dower, or thirds, of the estate-tail. 3. That the husband of a female tenant in tail may be tenant by the curtesy of the estate-tail. 4. That an estate-tail may be barred, or destroyed, by a fine, by a common recovery, or by lineal warranty descending with assets to the heir.

Thus much for the nature of estates-tail: the establishment of which family-law (as it is properly styled by Pigott) occasioned infinite difficulties and disputes. Children grew disobedient when they knew they could not be set aside: farmers were ousted of their leases made by tenants in tail; for if such leases had been valid, then, under colour of long leases, the issue might have been virtually disinherited: creditors were defrauded of their debts; for, if tenant in tail could have charged his estate with their payment, he might also have defeated his issue, by mortgaging it for as much as it was worth: innumerable latent entails were produced to deprive purchasers of the lands they had fairly bought; of suits in consequence of which, our ancient books are full: and treasons were encouraged, as estates-tail were not liable to forfeiture longer than for the tenant's life. So that they were justly branded as the source of new contentions and mischiefs unknown to the common law; and almost universally considered as the common grievance of the realm. But as the nobility were always fond of this statute, because it preserved their family-estates from forfeiture, there was little hope of procuring a repeal by the legislature; and therefore, by the connivance of an active and politic prince, a method was devised to evade it.

About 200 years intervened between the making of the statute *de donis*, and the application of common recoveries to this intent, in the 12th year of Edward IV.; which were then openly declared by the judges to be a sufficient bar of an estate-tail. For though the courts had, so long before as the reign of Edward III. very frequently hinted their opinion that a bar might be effected upon these principles, yet it never was carried into execution; till Edward IV. observing (in the disputes between the houses of York and Lancaster) how little effect attainders for treason had on families whose estates were protected by the sanctuary of entails, gave his countenance to this proceeding, and suffered Taltarum's case to be brought before the court: wherein, in consequence of the principles then laid down, it was in effect determined, that a common recovery suffered by tenant in tail should be an effectual destruction thereof. These common recoveries are fictitious proceedings, introduced by a kind of *pia fraud*, to elude the statute *de donis*, which

which was found so intolerably mischievous, and which yet one branch of the legislature would not then consent to repeal : and that these recoveries, however clandestinely begun, are now become by long use and acquiescence a most common assurance of lands ; and are looked upon as the legal mode of conveyance, by which tenant in tail may dispose of his lands and tenements : so that no court will suffer them to be shaken or reflected on, and even acts of parliament have by a side-wind countenanced and established them.

This expedient having greatly abridged estates-tail with regard to their duration, others were soon invented to strip them of other privileges. The next that was attacked was their freedom from forfeitures for treason. For, notwithstanding the large advances made by recoveries, in the compass of about three-score years, towards unfettering these inheritances, and thereby subjecting the lands to forfeiture, the rapacious prince then reigning, finding them frequently re-settled in a similar manner to suit the convenience of families, had address enough to procure a statute, whereby all estates of inheritance (under which general words estates-tail were covertly included) are declared to be forfeited to the king upon any conviction of high-treason.

The next attack which they suffered, in order of time, was by the statute 32 Hen. VIII. c. 28. whereby certain leases made by tenants in tail, which do not tend to the prejudice of the issue, were allowed to be good in law, and to bind the issue in tail. But they received a more violent blow in the same session of parliament, by the construction put upon the statute of fines, by the statute 32 Hen. VIII. c. 36. which declares a fine duly levied by tenant in tail to be a complete bar to him and his heirs, and all other persons claiming under such entail. This was evidently agreeable to the intention of Henry VII. whose policy it was (before common recoveries had obtained their full strength and authority) to lay the road as open as possible to the alienation of landed property, in order to weaken the overgrown power of his nobles. But as they, from the opposite reasons, were not easily brought to consent to such a provision, it was therefore couched, in his act, under covert and obscure expressions. And the judges, though willing to construe that statute as favourably as possible for the defeating of entailed estates, yet hesitated at giving fines so extensive a power by mere implication, when the statute *de donis* had expressly declared that they should not be a bar to estates-tail. But the statute of Henry VIII. when the doctrine of alienation was better received, and the will of the prince more implicitly obeyed than before, avowed and established that intention. Yet, in order to preserve the property of the crown from any danger of infringement, all estates-tail created by the crown, and of which the crown has the reversion, are excepted out of this statute. And the same was done with regard to common recoveries, by the statute 34 and 35 Hen. VIII. c. 20. which enacts, that no feigned recovery had against tenants in tail, where the estate was created by the crown, and the remainder or reversion continues still in the crown, shall be of any force and effect. Which is allowing, indirectly and collaterally, their full force and effect with respect to ordi-

VOL. X.

nary estates-tail, where the royal prerogative is not concerned.

Lastly, by a statute of the succeeding year, all estates-tail are rendered liable to be charged for payment of debts due to the king by record or special contract ; as since, by the bankrupt-laws, they are also subjected to be sold for the debts contracted by a bankrupt. And, by the construction put on the statute 43 Eliz. c. 4. an appointment by tenant in tail of the lands entailed to a charitable use, is good without fine or recovery.

Estates-tail being thus by degrees unfettered, are now reduced again to almost the same state, even before issue born, as conditional fees were in at common law, after the condition was performed by the birth of issue. For, first, the tenant in tail is now enabled to alienate his lands and tenements by fine, by recovery, or by certain other means ; and thereby to defeat the interest as well of his own issue, though unborn, as also of the reversioner, except in the case of the crown : secondly, he is now liable to forfeit them for high treason : and, lastly, he may charge them with reasonable leases, and also with such of his debts as are due to the crown on specialties, or have been contracted with his fellow-subjects in a course of extensive commerce.

TAILZIE, in Scots law, the same with TAIL. See LAW, N° clxxx. g.

TALC, a class of fossil bodies, composed of broad, flat, and smooth laminae, or plates, laid evenly and regularly on one another ; easily fissile according to the site of these plates, but not at all so in any other direction ; flexible and elastic, bright, shining, and transparent ; not giving fire with steel, nor fermenting with acid menstrua ; and sustaining the force of a violent fire without calcining.

Venice talc is a soft smooth concrete, unctuous or spongy to the touch, of a whitish or pale-greenish colour, with a silver-like lustre, generally found in small pieces. It may be split into numerous fine plates or leaves ; which, singly, prove somewhat flexible and elastic, and perfectly pellucid, though the entire mass is commonly opaque, or at most only semitransparent. The smallest pieces are to be preferred ; the larger, however white and apparently pure on the outside, being apt to have specks or veins of heterogeneous matter in the internal part. This mineral has received the epithet *Venetian*, not from its being originally the product of Venice, but probably from that city having formerly been a principal mart for it. Though it may perhaps be met with in some parts of the Venetian dominions, it is more common in other countries ; in Muscovy, England, Norway, Hungary, Bohemia, Spain, and the Eastern nations.

Mr Newman examined talc with all the mineral acids, and with alkaline lixivia, which some report to have a greater action on it ; but without finding that either of them had any action at all ; the talc remaining undiminished in weight, and neither the talc or the liquors suffering any sensible alteration. He calcined it also with sulphur and common salt, with nitre, with sal ammoniac ; without any other effect than a little change in its colour. On trying to melt it with twice its weight of borax, the talc fell to the bottom as soon as the borax came into fusion. Alkaline salts,

Talc,
Talent.

and caustic alkalis taken in four times the weight of the talc, succeeded no better; this refractory earth refusing to unite with them: the salts being afterwards deliquescent in the air, the addition of acids occasioned no precipitation, which they must have done if the alkalis had taken up in fusion any part of the talc.

Here Dr Lewis observes, that Newman seems to have failed in these experiments from using too large a proportion of the salts and too weak a heat. Venice talc, with half its weight of alkaline salt, may, in a strong fire, be brought into perfect fusion, though not to perfect transparency: with equal its weight, or less, of borax, it runs into a beautiful, pellucid, greenish yellow glass. Talc does not melt with any other earth, nor even bake or cohere with any but the argillaceous: Mixtures of it with them all are nevertheless brought into fusion by a remarkably less quantity of saline matter than the ingredients separately would require. Thus equal parts of talc and chalk, with only one-fourth their weight of borax, melt in no very vehement heat, into a fine transparent greenish glass, of considerable hardness and great lustre. On substituting gypseous earths, as the lapis specularis, to chalk, the fusion was as easy, and the glass as beautiful; in colour not green, but yellow, like the topaz. Talc, with half its weight of sand, and a quantity of nitre equal to both, yielded also a transparent topaz-yellow glass. Several further experiments on talc may be seen in a Memoir by Mr Pott in the Mem. de l'Acad. de Berlin, 1746.

Talc is employed, in those places where it is found in any considerable quantity, in compositions for earthen vessels; and by some for tests and cupels. From its smoothness, unctuousity, and brightness, it has been greatly celebrated as a cosmetic; and the chemists have submitted it to a variety of operations, for procuring from it oils, salts, tinctures, magisteries, &c. for that intention. But all their labours have been in vain; and all the preparations sold under the name of *talc* have either contained nothing of that mineral, or only a fine powder of it.

The pulverization of this mineral is attended with some difficulty. The more brittle pieces may be pulverized pretty easily; but the very tough and flexible scarce at all; nor is heating the mortar and pestle red-hot, which some recommend, of any advantage. The most commodious method of reducing it into fine powder, is, by cautiously filing or grating it with a fish-skin.

Besides the white and greenish talcs treated of, there are yellow, red, and black foliaceous concretes, distinguished by the same name; but these are in general rather of the gypseous than talcy kind. Thus the black talc mentioned by Hoffman, which laid on burning coals falls into leaves and acquires a golden colour, seems to be a species of lapis specularis. Those of a yellow colour have been called *solar talcs*, and imagined to be impregnated with a sulphur of gold; which some of the chemists have pretended to extract by spirit of salt or aqua regis. But the yellow tincture which these minerals communicate, and the red sublimate which arises on distilling the solutions, proceed entirely from a ferruginous matter, common to these with other coloured earths.

TALENT, a money of account among the ancients.

See COIN, and MONEY.—Among the Jews a talent in weight was equal to 60 maneh, or 113 lb. 10 oz. 1 dwt. and 10½ grains.

TALIACOTIUS (Gasper), chief surgeon to the great duke of Tuscany, was born at Bononia in Italy in 1553. He wrote a Latin treatise intitled *Chirurgia nota de curis membri*, in which he teaches the art of engraving noses, ears, lips, &c. giving representations of the instruments and proper bandages; tho' many are of opinion that he never put his art in practice. However, his doctrine is not singular; for he shows that Alexander Benedictus, a famous chirurgical writer, described the operation before.

TALIO, (*lex talionis*), a species of punishment in the Mosaic law, whereby an evil is returned similar to that committed against us by another; hence that expression, "Eye for eye, tooth for tooth." This law was at first inserted in the 12 tables amongst the Romans; but afterwards set aside, and a power given to the prætor to fix upon a sum of money for the damage done.

TALISMANS, magical figures cut or engraved with superstitious observations on the characters and configurations of the heavens, to which some astrologers have attributed wonderful virtues, particularly that of calling down celestial influences. The talismans of Samothrace, so famous of old, were pieces of iron formed into certain images, and set in rings; these were esteemed preservatives against all kinds of evils. There were likewise talismans taken from vegetables, and others from minerals.

TALLAGE (*tallagium*), from the French *taille*, is metaphorically used for a part or share of a man's substance carved out of the whole, paid by way of tribute, toll, or tax.

TALLOW, in commerce, the fat of certain animals melted down and clarified, so as to be fit for making candles, &c.

TALLY, is a stick cut in two parts, on each whereof is marked, with notches or otherwise, what is due between debtor and creditor, as now used by brewers, &c. And this was the ancient way of keeping all accounts, one part being kept by the creditor, the other by the debtor, &c. Hence the tallier of the exchequer, whom we now call the *teller*. But there are two kinds of tallies mentioned in our statutes to have been long used in the exchequer. The one is termed *tallies of debt*, which are in the nature of an acquittance for debts paid to the king, on the payment whereof, these tallies are delivered to the debtors, who carrying them to the clerk of the pipe-office, have there an acquittance in parchment for their full discharge. The other are *tallies of reward or allowance*, being made to sheriffs of counties as a recompence for such matters as they have performed to their charge, or such money as is cast upon them in their accounts of course, but not leviable, &c. In the exchequer there is a tally-court, where attend the two deputy chamberlains of the exchequer, and the tally-cutter: and a tally is generally the king's acquittance for money paid or lent, and has written on it words proper to express on what occasion the money is received.

TALLY-Man, a person that sells or lets goods, clothes, &c. to be paid by so much a week.

TALMUD, among the Jews, a collection of the doc-

Taliacotius
Talmud.

Talpa
||
Tamerlane. doctrines of their religion and morality. It is the *corpus juris*, or body of the laws and customs of the Jews, who esteem it equal to the Scriptures themselves.

TALPA, the MOLE; a genus of quadrupeds belonging to the order of feræ. There are six fore-teeth in the upper jaw, and eight in the under jaw; with one large dog-tooth, and four smaller ones. There are two species, viz. 1. The caudata, or common mole, with a tail, and five toes on each foot. It is a native of Europe; lives under ground; burrows with vast rapidity with its fore-feet, flinging the earth back with its hind feet: has the sense of smelling exquisite, which directs it to its food, worms, insects, and roots. It does vast damage in gardens, by flinging up the soil and loosening the roots of plants. It is most active before rain, and in winter before a thaw, worms being then in motion. It breeds in the spring, and brings four or five young at a time: it makes its nest of moss, a little beneath the surface of the ground, under the greatest hillock: raises no hillocks in dry weather, being then obliged to penetrate deep after its prey. It makes a great scream when taken. *Palma christi* and white hellebore, made into a paste, and laid in their holes, destroys them. None in Ireland.

2. The asiatica has no tail, and but three toes on the feet. It is of a beautiful green and gold colour, variable with the light. It is a native of Asia.

TAMANDAU, in zoology. See MYRMECOPHAGA.

TAMARINDUS, the TAMARIND-TREE; a genus of the monogynia order, belonging to the triandria class of plants. There is but one species, viz. the Indica, a native of both the Indies, growing to a great size in those places where it is native. The stem is very large, covered with a brown bark, and dividing into many branches at the top. The branches are garnished with winged leaves, consisting of 16 or 18 pair of lobes, without a single one at the end. The lobes are about half an inch long, and $\frac{1}{8}$ th of an inch broad; of a bright green colour, a little hairy, and sit close to the midrib. The flowers come out from the side of the branches, five, six, or more together upon the same footstalk in loose bunches. They are composed of five petals, one of which is reflexed upwards like the standard in some of the butterfly-flowers; two others stand on each side like wings, and the other two are turned downwards. The flowers are succeeded by thick compressed pods, two, three, four, or five inches long; having a double skin or cover, and swell in every part where the seeds are lodged; full of an acid stringy pulp, which surrounds smooth compressed angular seeds. The plants are easily propagated by seeds, in the countries where they grow; but in this country require the treatment of other exotics. The pulp is much used in medicine as an agreeable cooling purgative. The tamarinds which come from the East Indies are black and preserved without sugar, whence they are less agreeable to the taste than the brown ones which are brought from the West Indies, and require sugar to preserve them.

TAMERLANE, the name of a celebrated conqueror among the Moguls. He was originally the son of a shepherd, but by degrees raised himself to

be the greatest monarch of the age. See MOGULS, n^o 15. *et seq.*

TAMUS, BLACK BRIONY; a genus of the hexandria order, belonging to the diccia class of plants. There are two species; the most remarkable of which is the communis, or common black briony, growing naturally about hedges and in rough places in England. The young shoots are good eating when dressed like asparagus. The root is acrid and stimulating.

TAN, the bark of the oak chopped and ground in a tanning mill into a coarse powder, to be used in the tanning of leather. See TANNING.

TANACETUM, TANSY; a genus of the polygamia equalis order, belonging to the syngenesia class of plants. There are eight species; the most remarkable of which is the vulgare, or common yellow tansy, which grows naturally on the borders of fields and on dry banks in many places of Scotland and England. The stalk is three or four feet high, erect, stiff, and branched: the flowers are yellow, and terminate the branches in flat umbels. It has a bitter taste and aromatic smell. It is esteemed good for warming and strengthening the stomach; for which reason the young leaves have obtained a place among the culinary herbs, their juice being an ingredient in puddings, &c. It is rarely used in medicine, though extolled as a good emmenagogue. A drachm of the dried flowers has been found very beneficial in hysteric disorders arising from suppressions. The seeds and leaves were formerly in considerable esteem for destroying worms in children, and are reckoned good in cholics and flatulencies. In some parts of Sweden and Lapland, a bath with a decoction of this plant is made use of to assist parturition.

TANGENT of an ARCH, is a right line drawn perpendicularly from the end of a diameter, passing to one extremity of the arch, and terminated by a right line drawn from the centre through the other end of that arch, and called the *secant*. See GEOMETRY.

TANGIER, a port-town of Africa, in the empire of Morocco and kingdom of Fez, situated at the entrance of the Straits of Gibraltar, in W. Long. 7^o. N. Lat. 35. 40. In 1662, this place belonged to the Portuguese, and was given to king Charles II. upon his marriage with the Infanta of Portugal: but he, growing weary of the charge of keeping it, caused it to be blown up and destroyed in 1684; ever since which time it has been only a poor fishing town. Anciently it was called *Tingis*, and gave name to the province of Mauritania Tingitana.

TANNER, one who dresses hides by tanning them. See TANNING.

TANNER (Dr Thomas), an English prelate and celebrated antiquarian, born in 1674. He was admitted of Queen's college Oxford, where a similarity of taste for antiquities produced a close friendship between him and Edmund Gibson afterwards bishop of London. In 1697, he was chosen fellow of his college; and having already published some specimens of his skill in the antiquarian way, soon after became known to Dr Moore bishop of Norwich, who made him chancellor of his diocese. In 1722, he was made arch-

Tamus
||
Tanner.

Tanning.

deacon of Norwich, and in 1731 bishop of St Asaph. He died at Oxford in 1735; and after his death was published an elaborate work, said to have employed him for 40 years, under this title, *Bibliotheca Britannica Hibernica, sive de Scriptoribus qui in Anglia, Scotia et Hibernia, ad seculi XVII. initium floruerunt, &c.*

TANNING, is the art of preparing raw hides or skins for the hand of the currier, or for immediate use without any further operation.

The former part of this definition includes all leather used for the upper part of shoes, coaches, coach-harness, fadler-leather, &c. and the latter the manufacture of bin or backs, &c.

A considerable improvement has been made in the method of tanning leather by the late Dr Macbride of Dublin, from whose account of his discovery in the Philosophical Transactions, the following is extracted.

"The use of tanning is two-fold; first, to preserve the leather from rotting; and, secondly, to render it impervious to water.

"An infusion of any strongly-astringent vegetable will serve to tan leather, so far as to prevent its rotting; but if this vegetable does not contain a good deal of gum-resin, it will not answer for enabling it to keep out water: and hence it is that oak-bark, which is more abundant in the gummy-resinous part than any of our common indigenous astringents, is preferred to all other substances for the purpose of tanning.

"The tanners prepare their bark by gently drying it on a kiln, and grinding it into a very coarse powder. They then either use it in the way of infusion, which is called *ooze*; or they strew the dry powder between the layers of hides and skins, when these are laid away in the tan-pits.

"The *ooze* is made by macerating the bark in common water, in a particular set of holes or pits, which, to distinguish them from the other holes in the tan-yard, are termed *letchers*.

"The first operation of the tanner is to cleanse his hides from all extraneous filth, and remove any remains of flesh or fat which may have been left behind by the butcher.

"The hair is next to be taken off; and this is accomplished either by steeping the hides for a short time in a mixture of lime and water, which is termed *liming*; or by rolling them up close and piling them in heaps, where they quickly begin to heat and putrify. The hair being loosened, is scraped off; and the tanner proceeds to the operation called *steepling*, which consists in a further scraping with a particular kind of knife contrived for the purpose, and cutting away the jagged extremities and ossal parts, such as the ears and nostrils.

"The raw leather is then put into an alkaline ley, in order to discharge the oil or fat, and render its pores more capable of imbibing the *ooze*. The tanners of Ireland generally make their ley of pigeon's dung: but a more active one may be prepared from kelp or pot-ash; taking care, however, not to make it too strong of the ashes, nor to allow the leather to remain too long in the ley.

"The oil being sufficiently discharged, the leather is ready for the *ooze*, and at first is thrown into smaller holes, which are termed *handlers*; because the

hides or skins, during this part of the process, are taken up from time to time, and allowed to drain: they continue to work the leather in these handlers, every now and then stirring it up with the utensil called a *plunger*, which is nothing more than a pole with a knob at the end of it, until they think proper to lay it away in the vatts. In these holes, which are the largest in the tan-yard, the leather is spread out smooth, whereas they toss it into the handlers at random; and between each layer of leather they sprinkle on some powdered bark, until the pit is filled by the leather and bark thus laid in *stratum super stratum*: *ooze* is then poured on, to fill up interstices; and the whole crowned with a sprinkling of bark, which the tanners call a *heading*.

"In this manner the leather is allowed to macerate, until the tanner sees that it is completely penetrated by the *ooze*; when this is accomplished (which he knows by cutting out a bit of the thickest part of the hide) the manufacture is finished, so far as relates to tanning, since nothing now remains but to dry the goods thoroughly, by hanging them up in airy lofts built for the purpose. Such in general is the process for tanning calf-skins, and those lighter sorts of hides which are called *batts*; but the large, thick, heavy hides, of which the strongest and most durable kind of sole-leather is made, require to have their pores more thoroughly opened before the *ooze* can sufficiently penetrate them. For this purpose, while the hides are in the putrescent state, from being allowed to heat in the manner already mentioned, and well soaked in an alkaline ley, they are thrown into a four liquor, generally brewed from rye, in order that the effervescence which necessarily ensues may open the pores.

"The tanners term this operation *raising*, as the leather is considerably swelled, in consequence of the conflict between the acid and alkali. This is an English invention; for it appears from M. De la Lande, who was employed by the Royal Academy of Sciences to write on the art of tanning, that the foreign tanners know nothing of this branch of the business: indeed, their whole process, according to his account, is slovenly, and even more tedious than our common method, and must make but very indifferent leather.

"When the raising is accomplished, the leather is put into the handlers, and worked in them for the requisite time; then laid away in the vatts, and there left to macerate until the tanning is found to be completely finished, which, for the heaviest kind of leather, such as this of which I am now speaking, requires from six to last full two years.

"It is this tediousness of the process which enhances the value of leather; and the returns being so slow, the trade of tanning never can be carried on to advantage but by persons possessed of a large capital: therefore, one sure way of increasing the number of tanners, and of course of bringing down the price of their manufacture, is to shorten the process; and if at the same time we can improve the quality of the leather, and save somewhat in the expence of tanning materials, the public will be essentially benefited in respect to one of the necessary articles of life.

"All this can be done by pursuing the following method, which may be introduced into any common tan-yard.

"With

Tanning.

" With respect to time, it is possible, in the way that I have found out, to finish leather in a fourth part of what is required in the ordinary process; for I have repeatedly had calf-skins tanned in a fortnight or four weeks, which in the common way could not be done in less than from two to four months.

" I shall not pretend, however, to affirm, that that business can be carried on in the large way with such expedition; because a great deal of this abridgment of time was probably owing to frequent handling and working of the leather: but I am confident, and know it from four years experience, that in the ordinary course of business, and in a common tan-yard, the tanner may save at least four months out of twelve, produce better leather, and find his bark go much farther than in the old way of tanning.

" As the new method of tanning depends on this principle, 'That lime-water extracts the virtues of oak-bark more completely than plain water;' the first thing in which the tanner is to be instructed, is the making of lime-water.

" 1. Provide a large vessel, in the nature of a cistern, whose depth shall be at least twice its diameter, and of a capacity adapted to the extent of the tan-yard.

" 2. This cistern must be fixed in a convenient corner of the yard, under a shed; and should stand so as that the liquor which is to be drawn off from it may run freely into the latches.

" 3. There must be a cock fixed in the side of the cistern, about a foot from the bottom, to let off the contents; and there must be a hole in the bottom of it, of five or six inches diameter, which is to be stoppered with a plug. Let this hole open over a gutter.

" 4. The cistern must be covered with a flooring of boards, strong enough to bear a man's weight; and from side to side of this lid there must be an opening of two or three feet wide.

" 5. If it can be so contrived that a water-pipe may be led into the cistern, it will save the servants a good deal of trouble; but if this cannot be done, a pump must be fixed in the most convenient way, for the purpose of filling it from time to time.

" 6. The cistern being once fixed (which is all the additional apparatus that the new method of tanning requires) the making of lime-water will be found extremely simple and easy.

" 7. You are first to fill the cistern with water; and then, for every hoghead that it may contain, throw in ten or a dozen pounds weight of unslaked lime.

" 8. Mix the lime thoroughly with the whole body of the water, by stirring it exceedingly well from the bottom, with a bucket and plunger, until you perceive that the lime is completely diffused, and the whole mixture grows as white as milk; leave it then to settle for a couple of days, that the undissolved part of the lime may entirely subside, and the water become perfectly limpid, and clear as rock-water. Your lime-water will then be fit for immediate use.

" 9. The cock, as already mentioned, is to be fixed at least twelve inches from the bottom of the cistern, in order that only the limpid part of the lime-water may run off; and the use of the hole in the bottom, which is ordered to be stoppered with a plug, is to

let off the gross and insoluble remains of the lime, as often as it may be found necessary to clean out the cistern.

" 10. When the first brewing (as it may be termed) of lime-water is all expended, you are to fill up the cistern with water a second time; stir up the lime from the bottom with the bucket and plunger, so as to mix it thoroughly with the whole body of the water, as before directed, and then leave it to subside for the requisite time. Thus you will have a second brewing of lime-water; and you may go on in the same manner to make a third, fourth, fifth, or perhaps a sixth or more brewings, from the original quantity of lime; provided you shall find the lime-water continue sufficiently strong.

" 11. There are two ways of knowing when lime-water is sufficiently strong. The one is by the taste, and this a little practice will teach you to distinguish; the other is, by observing a certain solid scum, like the flakes of very thin ice, which collects and forms itself on the surface of the lime-water.—As long as you find this solid scum floating on the top of the water in the cistern, so long you may conclude that there is no necessity for throwing in fresh lime.

" 12. But when the scum ceases to appear, or you find from the taste that the lime-water is not so strong as it ought to be, you must then take out the plug from the bottom of the cistern, and clear it by sweeping away the gross remains of lime: and after you have cleaned the cistern, begin your brewings of lime-water anew, and proceed in the manner already directed, as to stirring up the lime, and leaving it to settle for the necessary time, so as to have your lime-water perfectly limpid. In this manner you may go on from year to year, and constantly keep yourself in stock with respect to lime-water.

" 13. It is this lime-water which is now to be used in making your ooze instead of the plain common water; and this is all the difference between the old and the new method of tanning; for when your ooze is prepared, by steeping your bark in lime-water (in the latches, as you do at present, only running it through two latches) you are to make use of it in the very same way that you have hitherto used the common ooze, there not being the least variation required with respect to any of the previous management before the skins or hides are fitted for the ooze. Every thing that relates to cleaning, liming, fleshing, &c. is to be conducted precisely as in the old or common method of tanning; and the goods are to be worked in the handlers for the requisite time, and then laid away in the wats, with layers and headings of bark, just as you now practice; and when you observe that the leather is sufficiently penetrated with the ooze, that is to say, completely tanned, you will take it up, dry it, and afterwards dress it according to the different uses for which it is intended. You are always to observe, however, that the ooze is to be turned from one litch on another before it is used, otherwise it will be apt to blacken the leather.

" 14. What has been hitherto said relates only to butts and calf-skins: as to soal-leather, which is prepared for the ooze by steeping it in some sour liquor, in order to open its pores, and raise it (according to the

Tanning. the tanner's phrase), the new method requires a different practice from the old one.

"15. In the old method, the tanners made use of sourings brewed generally from rye or some other grain. But these liquors are not only troublesome to brew and to ferment, but they are always uncertain as to the degree of sourness or strength, which depends on the state of the weather and other variable circumstances: these liquors are moreover exceedingly apt to rot the leather; and, without great care, may injure it very materially in its texture.

"16. To obviate these inconveniences, you are to imitate the bleachers of linen, who make use of a sour prepared by diluting the strong spirit of vitriol (vulgarily, but improperly, termed *oil of vitriol*) with a sufficient quantity of plain water.

"17. It was not without much difficulty that the bleachers could be prevailed on to quit their old sourings, made either, like yours, of rye or barley, or of four butter-milk, from a groundless fear that the vitriolic souring would corrode their cloth; but the experience of many years has convinced them of their error, and now no other souring is used. In like manner the tanners at first may some of them be afraid to use the vitriol; but a little practice will show how far superior this souring is to what they have hitherto used. They will never find it subject to any change, in respect to strength, from variations of weather or different degrees of heat; and so far from tending to rot the leather, it gives unusual firmness; and the soles which are raised by the vitriolic sourings are remarkably sound, and always free from the slightest degree of rotteness. Besides, the same sour may do for many parcels of leather, by adding a little vitriol to it; and it need only be thrown away, when it becomes too dirty for use by the frequent succession of hides.

"18. A wine-pint of the strong spirit of vitriol, which will not cost more than nine or ten pence, is sufficient for fifty gallons of water to prepare the souring at first: therefore all you have to do, in raising the soles, is only to prepare them before-hand in the usual way; and, when they are fitted for the souring, mix up a quantity of vitriol and water, according to the number of hides that you require to have raised, still observing the proportion of a pint to fifty gallons, which will be enough if the vitriol be of the due degree of strength. The hides may lie in the souring till you find them sufficiently raised: for they will be in no danger of rotting, as they would be in the common corn-sourings, which in time might turn putrid, and rot the leather; whereas the vitriolic souring keeps off putrefaction.

"19. When you find your hides sufficiently raised, put them directly into the ooze, and go on with the tanning as in the old way; and you will see that the lime-water ooze penetrates raised leather even faster than it does butts or calf skins, allowance being made for their different degrees of thickness.

"20. Let it be now supposed that you have your cistern fixed, your lime-water prepared, and some latches full of lime-water ooze, which has been run through two latches in order that the lime-water may completely spend its force on the bark; you are not to throw away what common ooze you have in stock

in the yard, but only as it shall be spent; then, indeed, you are to throw it away, and supply its place with the lime-water ooze.

"21. In a very few days you will perceive the difference between the activity of the two oozes, the new and old, with respect to penetrating the leather: and thus, without any kind of loss or waste, you will get rid of all your old liquors, and come speedily into a full stock of the ooze made with lime-water; and after you have got the new method established, your business will go in a regular course, and one parcel of goods will succeed another, as fast as you can manufacture and dispose of them.

"22. Though it is possible to tan small parcels of leather, by way of experiment, by the use of lime-water ooze, in a fourth part of the time which is required if only common ooze be made use of; yet the business of a large tan-yard cannot be carried on with so much expedition: but even in large works, and in the common course of business, soal-leather can be completely tanned and finished in from eleven to fifteen months, according to the different weight and thickness of the hides; butts, in from eight to twelve months; and calf-skins, in from six to twelve weeks: in general, the tanner may save at least a third of the time that has hitherto been required.

"23. The leather which is manufactured in the new way is of a superior quality to that of the old tannage, especially the soal-leather, which wears remarkably well, and never shows the least sign of rotteness.

"24. Let it always be remembered, that the lime-water is never to be used but when it is sufficiently strong, and as clear as rock-water.

"25. Whenever you make fresh ooze, you must always use fresh lime-water, and run the ooze through two latches; and the lime-water ooze, when spent from laying on the leather, is never to be returned back upon the bark which is in the latches, (as you now return your spent ooze), but must always be thrown away, as being entirely useless; for which purpose you must contrive a gutter in the tan-yard to carry off the spent ooze.

"26. The latches ought to be under cover, lest the rain get into them and weaken the ooze; and if the handlers are sheltered, it will be so much the better; but it is of no importance to cover the vats, provided, when the leather is laid away in them, they are kept constantly full to the brim.

"27. You must always take care to have a sufficient stock of unslaked lime by you, (for if it be slaked it will not answer to make lime-water): therefore get your lime fresh, if possible, from the kiln, and immediately pack it in any kind of old dry casks. Weigh one of these casks, and it will enable you to ascertain the quantity of lime necessary to be thrown into the cistern each time you begin a fresh brewing of your lime-water, and thus save you the trouble of repeated weighings; not that there need be much nicety about the quantity of lime, a score of pounds over or under making no sensible difference in the strength of the lime-water.

"28. Any expence you may be at in procuring lime, which even in the largest tan-yards can amount but to a trifle, will be amply compensated by the saving

Tanning,
Tantalus.

of bark; because that lime-water so completely exhausts the bark, and makes it go so much farther than when the ooze is made only of plain water. As a proof of this, you may make a pretty strong ooze from the tan or spent bark, which you now consider as completely exhausted, by infusing in it lime-water."

The leather, when only tanned, is not sufficiently soft and pliable to answer a number of purposes. The currier's province is to reduce the leather to the proper thickness, pliability, and colour, requisite for the different uses to which it is applied: and though there is a material difference in the method of manufacturing the several kinds, and a good deal of dexterity required; yet what could be here said of them would be of little use to those who are unacquainted with the business. We shall therefore reduce all we are to say on this subject to a general detail of the process.

The leather, after it has dripped some time from the tan-pit, is shaven on an upright beam with a knife whose edge is turned on the one side, and with which the currier can take down the leather in the same manner as a wrignt can take a shaving from a piece of wood with his plane. After the currier has thus levelled the hide or skin to his purpose, (which is always done on the flesh-side), he spreads it out on a stone or table made for the purpose, and there scours it on the grain-side from all the loose tan, and other stuff that may hurt the beauty of the grain. He then puts on a certain quantity of oil on both grain and flesh-side, for the purpose of softening the fibres, and at the same time making them tough, and hangs it up to dry. When it is sufficiently dry, there is a thin shaving again taken off the flesh-side, in order to clean or brighten it up; and then it is rubbed backward and forward upon a table by the currier with a nicked or furrowed board, keeping the leather always doubled at the place where he rubs, till it be made soft and pliable to his intention. This last part of the operation is properly called *currying*, and it is from this that the business gets its name. As to the colour, the leather is fair or dark in proportion to the quantity of oil laid on, if the tanning has been properly performed, and the currier do not neglect some material part of his duty. Carriers seldom dye any colour but black, which is done with copperas and a very little logwood.

TANTALUS, in fabulous history, king of Phrygia and Paphlagonia, was the son of Jupiter and the nymph Pluto. He one day entertained the gods at his table; when, to prove their divinity, he served up his son Pelops cut in pieces. All the deities, except Ceres, perceived his cruelty and impiety, and would not touch his provisions. That goddess, whose thoughts were solely employed about her daughter Proserpine, inadvertently eat a part of his left shoulder. Pelops, however, was restored to life; and an ivory shoulder given him in the room of that which had been eaten; while Tantalus was thrown into Tartarus, where he was punished with perpetual hunger and thirst. He was chained in a lake, the water of which reached up to his chin, but retired when he attempted to drink. The branch of a tree loaded with fruit hung down even to his lips, but on his attempting to pluck the fruit the branch sprang upwards.

TANTALUS, in ornithology, a genus of birds belonging to the order of grallæ. The bill is long, subulated, and

somewhat crooked; the nostrils oval, the fore-part of the head bald from the eyes; the feet have four toes palmed on the under-part. There are seven species; of which the most remarkable is the ibis of the Egyptians. Mr Hasselquist informs us that it is of the size of a raven-hen. This bird is found in Lower Egypt, and is seen in great numbers during the overflowing of the Nile, in those places which the water does not reach, and afterwards in the places the water has deserted. It feeds on insects and small frogs, which abound in Egypt during the inundation of the Nile and for some time after, being by this means of great service to the country. They often assemble, especially mornings and evenings, in the gardens, in such numbers as to cover whole palm-trees. When this bird rests, it sits upright, so as to cover its feet with its tail, and raises the breast and neck.

TANTALUS's Cup. See **HYDROSTATICS**, n° 38.

TANZY, or **TANSY**, in botany. See **TANACETUM**.

TAPE-WORM. See **TENIA**.

TAPESTRY, a curious kind of manufacture, serving to adorn a chamber or other apartment, by covering or lining the walls thereof. It is a kind of woven hangings of wool and silk, frequently raised and enriched with gold and silver, representing figures of men, animals, landscapes, histories, &c.

The invention of tapestry is said to have come to us from the Levant; and this seems the more probable, in that the workmen concerned in it were called, at least in France, *sarrafins*, or *sarrafinois*. It is supposed that the English and Flemish, who were the first that excelled in making tapestry, might bring the art with them from some of the croisades, or expeditions against the Saracens. Be this as it will, it is certain that these two nations, especially the English, were the first who set on foot this noble and rich manufacture in Europe, now one of the finest ornaments of palaces, churches, &c. and therefore, if they may not be allowed the inventors, they have at least the glory of being the restorers of this so curious and admirable art, as gives a kind of life to wools and silks, scarce inferior to the paintings of the best masters.

Tapestry-work is distinguished by the workmen into two kinds, viz. that of high and that of low warp; though the difference is rather in the manner of working than in the work itself; which is in effect the same in both: only the looms, and consequently the warps, are differently situated; those of the low warp being placed flat and parallel to the horizon, and those of the high warp erected perpendicularly. The English anciently excelled all the world in the tapestry of the high warp; and they still retain their former reputation, tho' with some little change: their low warps are still admired; but as for the high ones, they are quite laid aside by the French. The French have three considerable tapestry-manufactures, besides that of the Gobelins; the first at Aubusson in Auvergne, the second is at Felletin in the Upper Marche, and the third at Beauvais. They were all equally established for the high and the low warp; but they have all laid aside the high warp excepting the Gobelins. There are admirable low warps in Flanders, generally exceeding those of France; the chief and almost only Flemish manufactures are at Brussels, Antwerp, Oudenard, Lille, Tournay, Bruges, and

Tapestry.

Vas.

The usual widths of tapestries are from two ells to three ells Paris-measure.

The Manufacture of TAPESTRY of the High Warp. The loom whereon it is wrought is placed perpendicularly: it consists of four principal pieces; two long planks or cheeks of wood, and two thick rollers or beams. The planks are set upright, and the beams across them, one at the top, and the other at the bottom or about a foot distance from the ground. They have each their trunnions, by which they are suspended on the planks, and are turned with bars. In each roller is a groove from one end to the other, capable of containing a long round piece of wood, fastened therein with hooks. The use of it is to tie the ends of the warp to. The warp, which is a kind of worsted, or twisted woollen thread, is wound on the upper roller; and the work, as fast as wove, is wound on the lower. Within side the planks, which are seven or eight feet high, fourteen or fifteen inches broad, and three or four thick, are holes pierced from top to bottom, in which are put thick pieces of iron, with hooks at one end, serving to sustain the coat-stave: these pieces of iron have also holes pierced, by putting a pin in which, the stave is drawn nearer or set further off; and thus the coats or threads are stretched or loosened at pleasure. The coat-stave is about three inches diameter, and runs all the length of the loom; on this are fixed the coats or threads, which make the threads of the warp cross each other. It has much the same effect here as the spring-stave and treddles have in the common looms. The coats are little threads fastened to each thread of the warp with a kind of sliding knot, which forms a sort of mesh or ring. They serve to keep the warp open for the passage of broaches wound with silks, woollens, or other matters used in the piece of tapestry. In the last place, there are a number of little sticks of different lengths, but all about an inch in diameter, which the workman keeps by him in baskets, to serve to make the threads of the warp cross each other, by passing them across; and, that the threads thus crossed may retain their proper situation, a packthread is run among the threads above the stick.

The loom being thus formed, and mounted with its warp, the first thing the workman does, is to draw on the threads of this warp, the principal lines and strokes of the design to be represented on the piece of tapestry; which is done by applying cartoons, made from the painting he intends to copy, to the side that is to be the wrong side of the piece, and then, with a black-lead pencil, following and tracing out the contours thereof on the thread of the right side; so that the strokes appear equally both before and behind.

As for the original design the work is to be finished by, it is hung up behind the workmen, and wound on a long staff from which a piece is unrolled from time to time as the work proceeds.

Besides the loom, &c. here described, there are three other principal instruments required for working the silk or the wool of the wool within the threads of the warp; these are a broach, a reed, and an iron-needle.

The broach is made of a hard wood, seven or eight inches long, and two-thirds of an inch thick, ending in a point with a little handle. This serves as a shuttle;

the silks, woollens, gold, or silver, to be used in the work being wound on it.

The reed or comb is also of wood, eight or nine inches long, and an inch thick on the back, whence it grows less and less to the extremity of the teeth, which are more or less apart, according to the greater or less degree of fineness of the intended work. Lastly, the needle is made in form of the common needle, only bigger and longer. Its use is to press close the wool and silks when there is any line or colour that does not fit well.

All things being prepared for the work, and the workman ready to begin, he places himself on the wrong side of the piece, with his back towards the design; so that he works as it were blindfold, seeing nothing of what he does, and being obliged to quit his post, and go to the other side of the loom whenever he would view and examine the piece, to correct it with his pressing-needle. To put silk, &c. in the warp, he first turns and looks at the design; then, taking a broach full of the proper colour, he places it among the threads of the warp, which he brings cross each other with his fingers, by means of the coats or threads fastened to the staff; this he repeats every time he is to change his colour. Having placed the silk or wool, he beats it with his reed or comb; and when he has thus wrought in several rows over each other, he goes to see the effects they have, in order to reform the contours with his needle, if there be occasion. As the work advances, it is rolled upon the lower beam, and they unroll as much warp from the upper-beam as suffices them to continue the piece: the like they do of the design behind them. When the pieces are wide, several workmen may be employed at once.

We have but two things to add: the first is, that the high-warp tapestry goes on much more slowly than the low warp, and takes up almost twice the time and trouble. The second is, that all the difference that the eye can perceive between the two kinds, consists in this, that in the low warp there is a red fillet, about one-twelfth of an inch broad, running on each side from top to bottom, which is wanting in the high-warp.

TAPIR, in zoology, by some accounted a species of *HIPPOTAMUS*, has the fore-hoofs divided into four, and the hind-hoofs into three parts. The nose extends far beyond the lower jaw, is slender, and forms a sort of proboscis; it is capable of being contracted or extended at pleasure, and its sides are fulcated. The extremities of both jaws end in a point, and there are ten cutting teeth in each. Between them and the grinders there is a vacant space; and there are 10 grinders in each jaw. The ears are erect, the eyes small, and the body is shaped like that of a hog. The back is arched; the legs are short; and the hoofs small, black, and hollow. The tail is very small. The animal grows to the size of a heifer half a year old. The hair is short: when young, it is spotted with white; when old, of a dusky colour.—It inhabits the woods and rivers of the eastern side of South America, from the Ithmus of Darien to the river of Amazons. It sleeps during day, in the darkest and thickest forests adjacent to the banks; and goes out in the night-time in search of food. It lives on grass, sugar-

Tapping gar. canes, and on fruits. If disturbed, it takes to the water; swims very well; or sinks below, and, like the hippopotame, walks on the bottom as on dry ground. It makes a sort of hissing noise. The Indians shoot it with poisoned arrows; they cut the skin into bucklers; and eat the flesh, which is said to be very good. It is a salacious, slow-footed, and sluggish animal. Gumi-la says, it will make a vigorous resistance if attacked, and scarce fails slaying the dogs which it can lay hold of.—Dampier and Bancroft give very faulty descriptions of this beast, imagining it to be the same with the hippopotame.

TAPPING, in general, the act of piercing a hole in a vessel, and applying a tube or canula in the aperture, for the commodious drawing off the liquor contained therein.

TAPPING, in surgery. See there, n° 487, 488.

TAR, a thick, black, unctuous substance obtained chiefly from old pines and fir-trees by burning them with a close smothering heat, much used in coating and caulking ships, &c. It is prepared in different parts of Germany, in North America, and in all countries where there is much wood. The wood is inclosed in a large oven, to the quantity of ten or more loads at a time: this stands within another oven called the *mantle*, the space between them receiving the fire. From the bottom of the inner oven there runs a gutter, by which the tar is conveyed off in proportion as it melts out from the wood. Along with the tar there runs out an acid spirit or juice, by means of which part of the oily matter becomes soluble in water; and it is owing to this that tar infused in water communicates to it a medical virtue. Tar when distilled yields a kind of essential oil called *oleum pini* and *oleum tade*, which is greatly valued by painters, varnishers, &c. on account of its drying quality: it soon thickens of itself almost to the consistence of a balsam.

Of late it has been found that the empyreumatic oil produced from pitcoal or culm answers the purposes of tar distilled from wood. There is, however, the same difference between the two that there is between a vegetable and a bituminous empyreumatic oil. The process is much the same as when wood is used.

TARANTO, a sea-port town of Italy, in the kingdom of Naples, and in the Terra de Otranto. It is a strong and populous place, with an archbishop's see, and the title of a principality. It is seated on a peninsula, and is defended by a strong castle; but the harbour is choked up, which has hurt it very much. From this town the spiders called *tarantulas* have their name, whose bite it was said could not be cured but by music and dancing; but this is now found to be false †. E. Long. 17. 25. N. Lat. 40. 45.

TARACON, an ancient, populous, and large town of France, in Provence, with a well-built castle, and a chapter composed of 15 canons; seated on the river Rhone, in a pleasant fertile country, over-against Beaucaire, with which it communicates by a bridge of boats. E. Long. 4. 45. N. Lat. 43. 48.

TARAZONA, a strong town of Spain, in the kingdom of Arragon, and on the frontiers of Old Castile, with a bishop's see. It is seated partly on a rock, and partly in a fertile plain, on the river Chiles. It was

VOL. X.

taken from the Moors in 1110. W. Long. 1. 29. N. Lat. 41. 55.

TARE, is an allowance for the outside package, that contains such goods as cannot be unpacked without detriment: or for the papers, threads, bands, &c. that inclose or bind any goods imported loose; or tho' imported in casks, chests, &c. yet cannot be unpacked and weighed neat.

TARGET, a kind of shield or weapon of defence made use of by the ancients.

TARGUM, a name whereby the Jews call the Chaldee paraphrases or expositions of the Old Testament in the Chaldee language. See BIBLE.

TARIF, a table or catalogue containing the names of different sorts of merchandize, with the duties to be paid as settled by authority amongst trading nations.

TARPA (Spurius Mecius), a Latin critic in the time of Julius Cæsar and Augustus. He had his tribunal in the temple of Apollo, where, with four assistants, he passed sentence on the works of the poets. Cicero and Horace make honourable mention of this critic.

TARPAULIN, a piece of canvas, well tarred over, to keep off the rain from any place. The term is also often applied in a burlesque sense to a person that has been all his life bred to the sea.

TARPEIAN, in Roman antiquity, an appellation given to a steep rock in Rome; whence, by the law of the twelve tables, those guilty of certain crimes were precipitated.

The rock took its name from Tarpeia, a vestal virgin who was killed by the Sabines, as related under the article ROME, n° 24.

TARQUIN the ELDER, king of Rome, succeeded Ancus Martius 615 B. C. He instituted a new order of senators, under the title of *Patres minorum gentium*. He signalized himself as a general, and discovered great taste and magnificence in embellishing the city of Rome. Pliny, who lived 800 years after him, speaks with astonishment of the subterraneous aqueducts which he caused to be constructed to carry off the filth from the city. Assassinated by the sons of Ancus Martius, 577 B. C. See ROME, n° 35—40.

TARQUIN the Proud, a tyrant and usurper, had rendered himself odious to the Romans by his pride and cruelty, when his son, Sextus Tarquinius, having ravished Lucretia, occasioned that well-known revolution which put an end to the monarchy, and established the republic of Rome. See the article ROME, n° 49, 51, &c.

TARTAR, the saline incrustation deposited on the insides of casks in which wine is kept. See CHEMISTRY, n° 291.

TARTAR Chalybeated. See CHEMISTRY, n° 299.

TARTAR Emetic. See CHEMISTRY, n° 455.

TARTAR Soluble. See CHEMISTRY, n° 294.

TARTAR Vitriolated. See CHEMISTRY, n° 119.

TARTARY, or **TATARY**, a very large country of Asia, situated between 57° and 160° of E. Long. reckoning from the west end of the isle of Ferro, and between 37° and 55° of Lat. It is bounded on the north by Siberia, or that part of Asia which belongs to Russia; on the west by the rivers Don, the Wol-

Tartary. ga, and Kama, which separate it from Russia; on the south by the Euxine and Caspian Seas, Kazarm, the two Buckarias, China, and Korea; and on the east, by the Oriental or Tartarian ocean. It extends from east to west the space of 104 degrees in longitude, or 4145 geographical miles; but its breadth is not proportionable, being not above 960 miles where broadest, and where narrowest 330.

This vast region is divided into two great parts; the one called the *Western*, the other the *Eastern Tartary*.

Western Tartary, which is much more extensive than the Eastern, containing 139 degrees of longitude out of 161, is inhabited by a great number of nations, or tribes of people, who are called *Mungles*, or *Mangals*, by themselves; and *Moguls* or *Tartars*, indifferently, by other nations.

The principal mountains, or rather chains of mountains, found in this part of Great Tartary, may be divided into three classes: first, those which run along the northern borders of it; and though, perhaps, not always contiguous, or of the same denomination, go under the general name of *Ulug Täg*, or *Dag*, that is, the *Great Mountain*. Secondly, those which make the southern bounds, and are called *Kichug Täg*, or the *Lesser Mountain*. The third great chain is called *Mount Altay*, lying nearly in the middle, between the Caspian Sea and Eastern Tartary, and extending between the other two, in about the 110th degree of longitude.

The principal rivers of Western Tartary, besides the Dnieper, Don, and Wolga, are the Jaik, or Yaik, and Yem, both descending from the Ulug Täg, and falling into the Caspian Sea on the north side: the river Ili, or Khonghis, which rises out of the Kichug Täg, on the borders of Little Buckaria, and runs north-west into the lake Palkasi, which is about 40 miles long, and 30 broad, in latitude 48°, longitude 97°, reckoning from the isle of Ferro: on this river the khan of the Eluths, or Kalmuks, usually resides: the river Irtsih, Irtis, or Erchi, which rises in Mount Altay, and runs westward, inclining to the north, between two branches of it, into the lake Sayfan, Saffan, or Ifan, called also *Honhotu-Nor*, 90 miles long from west to east, and 40 broad, in latitude 47° 30', longitude 104°; from whence issuing again, it passes north-west, through part of Siberia, and falls into the Obi, which has its source in the same mountain, about one degree to the north of that of the Irtsih; and seven or eight degrees to the north-east rises the Kem, or Jenisca, which runs westward for the space of seven or eight degrees, and then turning northward enters Siberia. The next river of note is the Selinga, which rises out of the lake Kofogol, Hutükto, or Khütükütü, which is 70 miles long from south to north, and 20 broad, in latitude 52°, longitude 118°, not far from the source of the Janisca, and taking a sweep southward, round by the east, falls northward into the lake Baykäl in Siberia, about 30 leagues north-west of the city Selinghinskoy, which stands upon it. Into the Selinga runs the Orkon, coming from the south-west; and into the Orkon the Tula, rising eastward in Mount Kentey. On the same mountain rises also two other rivers, viz. the Onon, called also by the Tartars *Saghalian Ula*, or the Dragon river, and by the Russians

Amür; which running north-eastward, and then taking a large sweep by the south, rolls along the bounds of Eastern Tartary, and falls into the eastern Ocean. On its banks stand two cities: Nerchinskoy, or Nipchew, a frontier of the Russians, almost due north of Pekin in China; and Saghalian Ula, possessed by the Chinese. Another large river in the Kerlon, or Kerulon, which running north-eastward, falls into the lake Kulon, or Dalay, which is 60 miles long from south-west to north-east, and 27 broad, in latitude 48° 30', longitude 135°, and issuing out again under the name of *Ergona*, or *Argun*, joins the Saghalian Ula, about 170 miles beyond Nerchinskoy. To these let us add the river Kalka, from whence, tho' small, the Kalka-Moguls, or Mongols, take their name. It rises in the mountains, separating Eastern from Western Tartary, and, running westward, falls into the lake Pair, and then into that of Kulon, before spoken of.

In the middle of a desert, on the banks of the river Irtsih, is a remarkable piece of antiquity called *SEDMY PALATY*, or *the seven palaces*. See that article.

Above the Sedmy Palaty, towards the source of the Irtsih, grows the best rhubarb in the world, without the least culture. In a plain of this country also, about eight or ten days journey from Tomsk in Siberia, are found many tombs and burying-places of ancient heroes, who in all probability fell in battle. These tombs are easily distinguished by the mounds of earth and stone raised over them; the Tartars say, Tamerlane had many engagements in this country with the Kalmuks, whom he in vain endeavoured to conquer. Many persons go from Tomsk, and other parts, every summer, to these graves, which they dig up, and find among the ashes of the dead considerable quantities of gold, silver, brass, and some precious stones, but particularly hilts of swords and armour. They find also ornaments of saddles and bridles, and other trappings for horses; and sometimes those of elephants. Whence it appears, that when any general or person of distinction was interred, all his arms, his favourite horse and servant, were buried with him in the same grave; this custom prevails to this day among the Kalmuks and other Tartars, and seems to be of great antiquity. It appears from the number of graves, that many thousands must have fallen in those places; for the people have continued to dig for treasure many years, and still find it unexhausted. They are, indeed, sometimes interrupted, and robbed of all their booty, by parties of Kalmuks, who abhor disturbing the ashes of the dead. Armed men on horseback, clad in brass, of no mean design and workmanship, with the figures of deer cast in pure gold, have been dug out of these tombs. They once discovered an arched vault, where they found the remains of a man, with his bow, lance, and other arms, lying on a silver table. On touching the body, it fell to dust. The value of the table and arms was very considerable.

Great quantities of a kind of ivory, called by the natives *Mammens-horn*, are found in this country and in Siberia, on the banks of the Obi. They are commonly found on the banks of rivers that have been washed by floods. Some of them are very entire and fresh, like the best ivory in all respects, excepting only the colour, which is of a yellowish hue. In Siberia,

Tartary. ria they make snuff-boxes, combs, and divers sorts of turnery ware of them. Some have been found weighing above 100 pounds English.

The most considerable tribes in Western Tartary, next to the Kalmucks, are the Kalkas and Mungls, or Mongals, properly so called. The country of the Kalkas extends eastward, from mount Altay to the source of the river Kalka, whence they derive their name, in the borders of Eastern Tartary, and 139th degree of longitude. The territories of the Mungls, or Mongals, lie to the south of those of the Kalkas, between them and the great wall of China, to which empire both nations are subject. Besides these tribes, who are idolaters, of the religion of the Delay Lama, there are others, who possess that part of Western Tartary called *Turkestan*, the original country of the Turks and Turkmans, situated to the north of Great Bukharia and Karazm, between those countries and the dominions of the Eluths. Under Western Tartary also is comprehended Tibet, Thibet, or Tobutt, subject to the Delay Lama, or great high-priest of the Pagan Tartars and Chinese.

In all the vast region of Western Tartary there are but few towns, most of the inhabitants living under tents, especially in summer, and moving from place to place with their flocks and herds. They generally encamp near some river, for the convenience of water.

The air of this country is temperate, wholesome, and pleasant, being equally removed from the extremes of heat and cold. As to the soil, tho' there are many mountains, lakes, and deserts in it, yet the banks of the rivers, and the plains, some of which are of great extent, are exceeding fertile. The mountains, woods, and deserts, abound with venison, game, and wild fowl; and the rivers and lakes both with fish and fowl. In particular, here are wild mules, horses, and dromedaries, wild boars, several kinds of deer, a species of goats with yellow hair, squirrels, foxes; an animal called *hautchan*, resembling an elk; another called *chulon*, or *chelson*, that seems to be a sort of lynx; and a creature called *tael-pe*, as small as an ermine, of whose skins the Chinese make mantles to keep out the cold. Among other birds of extraordinary beauty, bred in this country, there is one called the *shonkar*, which is all over white except the beak, wings, and tail, which are of a very fine red. Notwithstanding the soil in many parts of Tartary is so luxuriant, yet, we are told, it does not produce a single wood of tall trees of any kind whatever, excepting in some few places towards the frontiers; all the wood that is found in the heart of the country consisting of shrubs, which never exceed the height of a pike, and even these are rare.

It is remarkable, that in all the vast dominions of Mongolia, there is not so much as a single house to be seen. All the people, even the prince and high-priest, live constantly in tents, and remove their cattle from place to place, as conveniency requires. These people do not trouble themselves with ploughing or digging the ground in any fashion, but are content with the produce of their flocks, though the soil is exceeding fine, and capable, by proper culture, of producing grain of several sorts.

In the country of the Mongals the grafs is very

thick and rank, and would, with little labour, make excellent hay. This grafs is often set on fire by the Mongals in the spring, during high winds. At such times it burns most furiously, running like wild-fire, and spreading its flames to the distance of perhaps 10 or 20 miles, till its progress is interrupted by some river or barren hill. The rapidity of those flames, their smoke and crackling noise, cannot easily be conceived by those who have not seen them. When any person finds himself to the leeward of them, the only method by which he can save himself from their fury, is to kindle immediately the grafs where he stands, and follow his own fire. For this purpose, every person is provided with flints, steel, and tinder. The reason why the Mongals set fire to the grafs, is to procure early pasture to their cattle. The ashes left upon the grafs sink into the earth at the melting of the snow, and prove an excellent manure; so that the grafs in the spring rises on the lands which have been prepared in this manner, as thick as a field of wheat. Caravans, travellers with merchandise, but especially armies, never encamp upon this rank grafs; and there are several instances of considerable bodies of men being put in confusion, and even defeated, by the enemy's setting fire to the grafs.

Eastern Tartary, according to the limits usually assigned it by historians and geographers, is bounded to the west by Western Tartary, or by that part possessed by the proper Mungls and Kalkas; on the north, by Siberia; on the east, by that part of the Oriental Ocean called the *Tartarian Sea*; and on the south by the same sea, the kingdom of Korea, and the Yellow Sea, which separates it from China. It is situated between the 137th and 160th degrees of longitude, being about 900 miles long from south to north, and near as many in breadth from west to east, yet but thinly peopled. This large region is at present divided into three great governments, all subject to the Chinese, viz. Shin-yang, or Mugden, Kurin-ula, and Taitfikar.

The government of Shin-yang containing all the ancient Lyau-tong or Quan-tong, is bounded on the south by the great wall of China and the Yellow Sea; on the east, north, and west, it is inclosed by a wooden palisade, seven or eight feet high, fitter to mark its bounds and keep out petty robbers, than to oppose an army.

The lands of this province are, for the general, very fertile, producing abundance of wheat, millet, roots, and cotton. They also afford pasture to great numbers of sheep and oxen, which are rarely seen in any of the provinces of China. They have indeed but little rice; yet, to make amends, there is plenty of apples, pears, hazel-nuts, filberds, and chestnuts, even in the forests. The eastern part, which borders on the ancient country of the Manchews and kingdom of Korea, is full of deserts and bogs. The principal cities of this government are Shing-yang or Mugden, Fong-whang-ching, Inden, Ichew, and Kingchew. This country was the original seat of the Tartar tribe of the Manchews, who have been masters of China above 100 years.

The government of Kirin-ula-hotun is bounded westward by the palisade of Lyau-tong; on the east, by the Eastern Ocean; southward, by the kingdom of

Tartary.

Tartary.

Korea; and on the north by the great river Saghalien: so that it extends no fewer than 12 degrees, and almost 20 degrees in longitude, being 750 miles in length, and 600 in breadth.

This vast country abounds in millet and oats, with a sort of grain unknown in Europe, called by the Chinese *may-sen-mi*, as being of a middle kind between wheat and rice. It is wholesome, and much used in those cold regions. There is but little wheat or rice here; but whether that is the fault of the soil or the inhabitants, we cannot assert. The cold begins much sooner in these parts than at Paris, whose latitude is near 50 degrees. The forests, which are very thick and large the nearer you advance to the Eastern Ocean, contribute not a little to bring it on and keep it up. The banks of the rivers here, in summer, are enamelled with a variety of flowers common in Europe, excepting the yellow lilies, which are of a most lively colour, in height and shape exactly resembling our white lilies, but are of a much weaker scent. But the plant which is most esteemed, and draws a great number of herbalists into these deserts, is the gin-seng*, called by the Manchews *arhota*; that is, the chief or queen of plants. It is highly valued for its virtues in curing several diseases, and all decays of strength proceeding from excessive labour of body or mind. For this reason it has always been the principal riches of Eastern Tartary; what is found in the north of Korea being consumed in that kingdom.

Formerly the Chinese used to get into the gin-seng country among the mandarins and soldiers continually passing; but, in 1700, the emperor Kang-hi, that his Manchews might reap this advantage, ordered 10,000 of his soldiers, encamped without the great wall, to go and gather it, on condition that each should give him two ounces of the best, and take an equal weight of fine silver for the remainder: by which means the emperor got in that year 20,000 pounds of it for less than one-fourth of the price it bears at Pekin. The root is the only part that is used medicinally. Its value is enhanced by its age, for the largest and firmest are the best. This country abounds also in fine fables, grey ermines, and black foxes.

One of the tribes of Tartars inhabiting this country are called the *Tu-pi Tartars*, whose manner of life is somewhat extraordinary. All the summer they spend in fishing: one part of what they catch is laid up to make oil for their lamps; another serves for their daily food; and the rest, which they dry in the sun, without salting, for they have no salt, is laid up for their winter's provisions, whereof both men and cattle eat when the rivers are frozen. Notwithstanding this diet, a great deal of strength and vigour appears in most of these poor people. Their raiment consists of the skins of fish, which, after dressing and dyeing of three or four colours, they shape and sew in so delicate a manner, that one would imagine they made use of silk, till, on ripping a stitch or two, you perceive an exceeding fine thong, cut out of a very thin skin. When the rivers are frozen, their sledges are drawn by dogs trained up for the purpose, and highly valued.

Although the Manchew language is as much used at the court of Pekin as the Chinese, and all public acts are drawn up in the one as well as the other; yet it began to decline, and would probably have been

lost, had not the Tartars taken great pains to preserve it, by translating Chinese books, and compiling dictionaries, under the emperor's patronage. Their language is singular in this respect, that the verb differs as often as the substantive governed by it: or, which is the same thing, to every different substantive they use a different verb; as for instance, when they would say, *make a verse, a picture, a statue*; for tho' the repetition of the same verb in discourse might be excusable, it is with them unpardonable in writing, as making a monstrous grating to their ears.

Another singularity of their language is the copiousness of it: for instance, besides names for each species of animals, they have words to express their several ages and qualities. *Judagen* is the general name for a dog; but *taiba* signifies a dog who has very long and thick hair both on his ears and tail; and *yolo*, a dog with a long thick muzzle and tail, large ears, and hanging lips. The horse, as more serviceable to them, has 20 times more names than the dog; almost every motion of him giving occasion to a different name. Where they could get that astonishing multitude of names and terms, is not easy to determine.

On the west are the Mungle, but in the two languages there are scarcely eight words alike. They understand nothing of the language of a few savage nations on the east and north. As to the Koreans, their language and letters being Chinese, have no resemblance to the Manchews. It is said, they have above 60 letters in their alphabet, but only one sort of character. They write from the top to the bottom of the paper, like the Chinese, but four different ways, according to the occasion, as in other countries. They commonly write with a pencil, though some use a kind of bamboo pen; but the pencil holds ink better, and moves more freely on the paper. The Manchews think their language the most elegant, as well as the most copious, in the world; and imagine there is no rendering the sense of it, much less the majesty of its style, in any other language: yet they cannot express all sounds, as they want the letters B and D, using P and T in their stead; nor can write words in which two consonants come together, without inserting a vowel between them. Their transitions likewise are so few, that they are much puzzled how to connect their written discourses. In other respects it must be allowed to be a masterly language, and as full of terms perhaps as the Arabic itself.

This country is but thinly peopled, and contains only four cities, namely, Kirinula-hotun or Khotun, Pedne or Petuna, Ningguta, and Putay-ula-hotun, which are very ill-built, and encompassed with no better than mud-walls. The first stands on the river Songari, and is the residence of the Manchew general, who has all the privileges of a viceroy, and commands the mandarines as well as the troops. Ningguta, which the family now reigning in China considers as its ancient patrimony, is situated on the Hürkapira, which runs northward into the Songari. Its name is compounded of two Tartarian words which signify seven chiefs, to express the rise of the Manchew kingdom, which was first established by seven brothers of the late emperor Kanghi's great-grandfather's father.

The tribe of the Manchews, who inhabit a part of

* See
PANAS.

Tartary. of Eastern Tartary, and are lords of all the other inhabitants thereof, are called by the Russians *Bogdoy*; and the emperor of China, *Bogdoy khan*, and *Amulon Bogdoy khan*.

The third government into which Eastern Tartary is divided, is that of *Tütsikar*. It is 740 miles long, and 600 broad; and belongs partly to China, and partly to Russia. The people are great hunters, dexterous archers, and pay their tribute in fable skins; each family being affixed two or three, or more a-year, according to the numbers of able persons.

This province is inhabited chiefly by three sorts of Tartars, the Manchews, the Solons, and *Tagüri*, of whom the first are masters. The *Tagüri* are a large robust people, but not very numerous. They live in houses or huts, and cultivate barley, oats, and millet. Their cattle are principally horses, dromedaries, oxen, cows, and sheep. They make much use of their oxen to ride on.

The Solons also are a brave robust people. Their dress is a short jacket of wolves skins, with a cap of the same; and they have long cloaks, made of fox or tigers skins, to defend them against the cold, especially of the night. They hang their bows at their backs. Their women ride on horseback, drive the plough, hunt stags and other game.

Besides the country towns or villages, there are three cities in the province of *Tütsikar*, namely, *Tütsikar*, *Merghen*, and *Saghalian-ula-hotun*. The garison of *Tütsikar*, the capital, consists of Manchews; but the inhabitants are mostly Chinese. According to their own account, they are all shamans, or conjurors, and invoke the devil with frightful cries. They give their dead two burials, first leaving a hole at top of the grave, where the relations daily bring victuals, which they convey to the mouth of the deceased with a spoon, and leave drink in small tin cups, standing round the grave. This ceremony holds for several weeks, after which they bury the body deeper in the ground.

Several rivers in this country produce pearls, which, tho' much cried up by the Tartars, would be little valued by Europeans, on account of their defects in shape and colour.

The kingdoms or countries of *Corea*, *Lyau-tong*, and *Nyu-che*, forming a part of *Katay*, *Kitay*, or *Cathay*, and by some included under Eastern Tartary, are more properly provinces of China, tho' they lie without the great wall.

Ufbeck Tartary. To the north and north-east of Persia lie the countries of *Karasm*, and Great and Little *Bukharia*, which being mostly subject to and inhabited by the tribe of *Ufbeck Tartars*, are commonly known by the general name of *Ufbeck Tartary*.

The kingdom of *Karasm* was known to the ancient Greeks, as appears from *Herodotus*, *Ptolemy*, and other authors of that nation, by the name of *Khorasmia*. At present it is bounded on the north by the country of *Turkistan*, and the dominions of the great khan of the *Eluths* or *Kalmuks*; on the east, by Great *Bukharia*, from which it is separated partly by the mountains of *Irdar*, and partly by the deserts of *Karak* and *Gaznah*; on the south, by the provinces of *Afshabad* and *Khorasan*, belonging to *Iran*, or *Persia* at large, from which it is divided by the river *Jihun*

or *Amu*, and sundry deserts of a vast extent; and on the west by the *Caspian Sea*.

It may be about 440 miles in length from south to north, and 300 from west to east; being situated between the 39th and 46th degrees of north latitude, and the 71st and 77th degrees of east longitude. The country consists, for the most part, of vast sandy plains, some of which are barren deserts, but others afford excellent pasture. There is good land in several of the provinces, where vines grow, and wine is made; but water being scarce, a great part of the country turns to no account.

Karasm owes all its fertility to three rivers and a lake. The rivers are the *Amu*, *Khesil*, and *Sir*. The *Amu*, as it is called by the *Ufbecks* and *Persians*, is the *Jihun* of the *Arabs*, and *Oxus* of the ancient *Greeks*. It has its source in those high mountains which separate Little *Bukharia* from the dominions of the Great *Mogul*; and, after passing through Great *Bukharia* and *Karasm*, divides into two branches, one of which falls into the *Khesil*, and the other into the *Caspian Sea*, towards the borders of the province of *Afshabad*. The *Amu* abounds with all sorts of excellent fish, and its banks are the most charming in the world. Along them grows those excellent melons and other fruits so much esteemed in *Persia*, the *Indies*, and *Russia*.

The river *Khesil* rises in the mountains to the north-east of the province of *Samarkant*, and falls into the lake of *Aral* or *Eagles*, 50 or 60 miles below its junction with a branch of the *Amu*. Its banks are exceeding fertile wherever they are cultivated.

The *Sir*, or *Daria*, rises in the mountains to the east of Little *Bukharia*, and after a long course westward, along the borders of the *Bukharias* and *Karasm*, falls at last into the lake *Aral*.

Karasm is at present inhabited by three sorts of people, the *Sarts*, *Turkmans*, and *Ufbeck Tartars*. With regard to the first of these, we are told, that they are the ancient inhabitants of the country, or those who were settled there before the *Ufbecks* became masters of it; and that they support themselves like the *Turkmans*, by their cattle and husbandry. The *Turkmans*, or *Turkomans*, came originally from *Turkellan*, or the parts of *Tartary* to the north of *Karasm* and Great *Bukharia*, towards the 11th century. They divided into two parties; one of which went round the north side of the *Caspian Sea*, and settled in the western parts of the *Greater Armenia*, from thence called *Turkomania*, or the country of the *Turkomans*. The second party turned south, and rested about the banks of the river *Amu* and the shores of the *Caspian Sea*, where they still possess a great many towns and villages, in the countries of *Karasm* and *Afshabad*.

The name of *Ufbecks*, which the ruling tribe of the *Tartars* of *Karasm* and Great *Bukharia* bear at present, is derived from one of their khans. The *Ufbecks* of *Karasm* are divided into several hords, and live for the most part by rapine; resembling in all respects those of Great *Bukharia*, excepting that they are much more rude and uncivilized. Like the *Turkmans*, they dwell in winter in the towns and villages which are towards the middle of *Karasm*; and in summer the greater part of them encamp in the neighbourhood.

Tartary.

Tartary,
Tartini.

bourhood of the Amu, or in other places where they can meet with pasture for their cattle, always watching for some convenient opportunity to rob and plunder. They never cease making incursions upon the adjacent territories of Persia or Great Bukharia, and are to be restrained by no treaties or engagements whatsoever. Although they have fixed habitations, yet, in travelling from one place to another, they carry with them all their effects of value, conformable to the way of living in use among their ancestors before they had settled dwellings.

Their Tartars, it is said, never ride without their bow, arrows, and sword, although it be in hawking or taking any other diversion. They have no arts or sciences among them, neither do they till or sow. They are great devourers of flesh, which they cut in small pieces, and eat greedily by handfuls, especially horse-flesh.

Their chief drink is four mare's milk, like that in use with the Nogays. They eat their victuals upon the ground, sitting with their legs double under them; which is their posture also when they pray.

All these tribes have abundance of camels, horses, and sheep, both wild and tame. Their sheep are extraordinary large, with great tails weighing 60 or 80 pounds. There are many wild horses in the country, which the Tartars frequently kill with their hawks. These birds are taught to seize upon the head or neck of the beast, which being tired with toiling to get rid of this cruel enemy, the hunter, who follows his game, comes up and kills him. Some travellers tell us, that the inhabitants of this country have not the use of gold, silver, or any other coin, but barter their cattle for necessities. Others tell us, that they have money, particularly a piece of silver called *tanga*, the value near the fourth-part of a crown. It is round, and has on one side the name of the country, and on the other that of the khan with the year of the hejrah. There are also, it is said, small pieces of copper, of different sizes, which answer to our pence, half-pence, and farthings.

As to the government of Karafm, the Usbecks being masters, it is commonly vested in divers princes of that tribe of the same house; of whom, notwithstanding, only one has the title of *khan*, with a kind of superiority over the others. This khan has no sort of dependence on him of Great Bukharia, or any other prince.

Bukharia, Bokharia, Bokaria, Bogaria, or Boharia, is the name given to all that region or tract of land lying between Karafm and the Great Kobi, or Sandy Desert, bordering on China. It is divided into the Great and Little Bukharia; for an account of which see the article BUKHARIA.

TARTINI (Signior), a very celebrated Italian composer and performer on the violin, was born at Pirano in Istria in 1692; where, having in his early youth manifested an attachment to an unworthy object, his father shut him up: it was during this confinement, that, amusing himself with musical instruments, he accidentally discovered the seeds of his musical talents. He was engaged in 1722 as a performer in the church of St Anthony at Padua, in which capacity he officiated as long as he lived; and wrote several treatises on music. A singular anecdote is re-

lated of him, which serves to show to what a degree his imagination was animated by a genius for composition. He dreamed one night, in 1713, that he had made a compact with the devil, who promised to be at his service on all occasions; and in the course of their acquaintance presented his new friend with his violin to try what kind of a musician he was. To his great astonishment, he heard the devil play a solo so exquisitely beautiful, that he awaked in a transport, and, seizing his fiddle, endeavoured in vain to express what he thought he had just heard: however, he then composed a piece, which is perhaps the best of all his works; and called it *The devil's sonata*. He died in 1770; and left to the professor Colombo the care of a posthumous work, of which, as Dr Burney relates, though it is chiefly mathematical, the theory of sound makes a considerable part.

TASSO (Torquato), a justly celebrated Italian poet, was born at Sorrento in the kingdom of Naples, in 1544. He was the son of Bernardo Tasso, the author of several ingenious compositions both in verse and prose; and of Portia de Rossi, a lady of an illustrious family of Naples.

His father being obliged to accompany the prince of Salerno to the emperor Charles V. upon a deputation from Naples to remonstrate against erecting the inquisition there, committed the care of his son, then three years old, to Angeluzza, a man of great learning; who, we are told, at this tender age began to teach him grammar: at four he was sent to the Jesuits college, and at seven was well acquainted with Latin and Greek. At 12 years of age he went from Rome to Mantua, where his father had entered into the service of the Duke Guglielmo Gonzaga: he had then completed his knowledge of the Latin and Greek languages; he was well acquainted with rhetoric and poetry, and a master of Aristotle's ethics; he had also studied the precepts of Mauritio Cataneo with particular attention, and ever after revered him as a second father.

He was soon after sent to the university of Padua; and, in his 18th year, published his *Rinaldo*, a poem written upon the plan of Homer's *Odyssey*. This extended his reputation throughout all Italy; but greatly displeased his father, who foresaw that it would seduce him from studies of more advantage. He went to Padua, to remonstrate against his apparent purpose of giving himself up to philosophy and poetry, and made use of many very harsh expressions, which Tasso heard with a patience and tranquillity that made the old gentleman still more angry: "Of what use is that philosophy on which you value yourself so much?" "It has enabled me (replied Tasso) to endure the harshness of your reproaches."

He soon after went to Bologna, by the invitation of the city and college; but in a little time returned to Padua at the pressing instances of Scipio Gonzaga, who had been elected prince of the academy that had been established in that city by the name of the *Ætherei*. He was incorporated into this society, and took upon himself the name of *Pentio*.

In this retreat he formed the design of his *Jerusalem Delivered*, invented the fable, disposed the parts, and determined to dedicate it to the house of Este; but whether to Alphonso II. the last duke of Ferrara,

Tasso.

rara, or his brother the cardinal Luigi, to whom he had already dedicated his *Rinaldo*, he was yet in doubt. Being pressed by both the brothers to reside with them at Ferrara, he consented. The duke gave him an apartment in his palace, where he lived in peace and affluence, and prosecuted his work; which he now determined to dedicate to the duke, and which was published by his patrons, book by book as he finished them.

When he was about 27, he published a pastoral comedy called *Aminta*; which was received with universal applause, as a master-piece in its kind, and is the original of the *Pastor Fido* and *Filli di Sciro*.

In the 30th year of his age he finished his *Jerusalem*, and the whole was reprinted and published together: the success of it was astonishing; it was translated into Latin, French, Spanish, and even the Oriental languages, almost as soon as it appeared.

But it was Tasso's fate to become wretched from the moment that he gained the summit of reputation: very soon after his *Jerusalem* was published, he lost his father, who died at Ostia upon the Po, the government of which place had been given him by the duke of Mantua; his *Jerusalem* was attacked by a swarm of ignorant, but petulant critics, who gave the preference to the rhapsodies of Pulci and Boyardo; and the perfidy of a friend drew upon him much greater misfortunes.

This friend was a gentleman of Ferrara, to whom Tasso had indifferently communicated some transactions of a very delicate nature concerning his patron the duke, with whom he lived. This secret being betrayed, Tasso reproached his friend for his treachery; and this reproach was retorted in such a manner as provoked Tasso to strike him. A challenge immediately ensued, and the opponents met and engaged; but during the encounter, three brothers of Tasso's antagonist came up, and all fell upon him together: Tasso defended himself so well, that he wounded two of them, and kept his ground against the others till some people came up and parted them. This made a great noise at Ferrara, where nothing was talked of but the valour of Tasso; and it became a kind of proverb, "That Tasso, with his pen and his sword, was superior to all men."

The duke being informed of the quarrel, banished the brothers from his dominions, confiscated their estates, and Tasso himself he shut up in prison under pretence of securing him from any future attacks of his enemies.

Tasso found means to escape from this confinement, after having suffered it about a year; and, being now about 34 years of age, retired to Turin, where he was soon known and recommended to the duke of Savoy, who showed him many marks of esteem and affection: but Tasso, fearing that the duke of Ferrara would require him to be delivered up, and that then the duke of Savoy would choose rather to comply than forfeit the friendship of that prince, precipitately set out for Rome alone, and without proper necessities for such a journey.

He got safe, however, to Rome; where he went directly to his friend Maurizio Cataneo, who received him with great kindness, and the whole city seemed to rejoice at the presence of so extraordinary a person.

He was visited by princes, cardinals, prelates, and all the learned in general. But being impatient of exile, he took measures to make his peace with the duke, and succeeded.

The duke received him with great appearance of satisfaction, and gave him fresh marks of his esteem. But Tasso having made some attempts on the princess Leonora, whom he has celebrated in several of his verses, the duke her brother, believing, or pretending to believe, that his ill conduct proceeded from a disordered understanding, caused him to be strictly confined in the hospital of St Anne. Tasso applied to the duke, by every friend he had, to release him from this confinement; but the duke coldly answered, that instead of endeavouring to procure the enlargement of a person in his condition, they ought rather to exhort him to submit patiently to such remedies as was judged proper for him. Tasso was certainly disordered in his mind, whether as the effect or cause of this confinement: he was conscious that he laboured under some distemper, and he believed the cause of it to be supernatural, and fancied himself haunted by a spirit that continually disordered his books and papers; to which, however, the tricks played him by his keepers might contribute. He continued, notwithstanding, to solicit the interposition of all the powers in Italy, to whom he could find means to apply, particularly the emperor and the pope; but without success. At last, after he had been a prisoner seven years, Vincentio Gonzaga prince of Mantua came to Ferrara among other great personages, during the festivals and rejoicings that were held there on the marriage of Caesar of Este with Virginia of Medici, procured his liberty, and took him with him to Mantua, he being then in the 42d year of his age.

At Mantua he lived about a year in great favour with the prince, and in all the splendour and affluence which the favour of great princes confers; but he was weary of a state of dependence, however splendid and luxurious; and therefore resolved to go to Naples, and endeavour to recover his mother's jointure, which had been seized by her relations when he went into exile with his father Bernardo. With this view, he procured letters of recommendation to the viceroy; and having taken leave of the prince of Mantua, he went first to Bergamo, where he staid some time, and from thence proceeded to Naples.

At Naples he immediately commenced a suit at law for the recovery of his right, and divided his time between a prosecution of that and his studies. But during the summer he retired to Bifaccio, with one Giovanni Batista Manso, with whom he had contracted an intimate friendship.

Tasso, who was now in his 45th year, appeared to Manso, while they were at Bifaccio, to be affected with a melancholy, which had very singular effects: he therefore very frequently questioned him about them; and Tasso told him that he had a familiar spirit, with whom he frequently and freely conversed. Manso treated this as an illusion, but Tasso still affirmed it to be real; and telling him that the spirit would meet and converse with him the next day, invited him to be present. Manso coming at the hour appointed, saw Tasso fix his eyes with great earnestness upon a window, and perceiving him to continue without motion.

Tasso. tion, he called him several times by his name; Tasso made no reply, but at length cried out with great vehemence, "There is the friendly spirit that is come to converse with me; look, and be convinced that what I have said is true." Manfo looked, not without some surprise, but saw nothing except the sunbeams which shone through the window: he was just going to ask where the pretended spirit was, when he was prevented by Tasso's speaking with great earnestness to some imaginary being, sometimes putting questions, and sometimes giving answers, in a manner so pleasing, and with such elevation of expression, that Manfo had no desire to interrupt him: the conversation at last ended by the supposed departure of the spirit; when Tasso, turning round to his friend, asked if his doubts were removed; to which he made no reply, being so much amazed that he gladly waived all farther conversation on the subject.

Finding his law-suit not likely to be soon determined, he went from Naples to Rome, where he continued about a year, in high favour with Pope Sextus Quintus; and then went to Florence, at the pressing invitation of Ferdinando grand duke of Tuscany, who had been cardinal at Rome when Tasso first resided there.

Having spent about another year at Florence, he returned again to Naples; and there applied himself to correct his *Jerusalem Delivered*. Soon after the publication of this work, Hippolito Aldrobandini succeeded Sextus Quintus to the papacy, by the name of *Clement the VIIIth*; and his two nephews, Cynthio and Pietro Aldrobandini, were created cardinals. Cynthio, who was a great patron of learning and genius, and had known Tasso when he last resided at Rome, prevailed with him once more to leave his retreat at Naples, and live with him in that city. Here he continued till his 50th year; and being then again weary of his situation, and desirous to prosecute his law-suit, he obtained permission to retire once more to Naples, where he took up his abode with the Benedictine fathers, in the convent of St Severin. Cardinal Cynthio, however, found means to recal him again to Rome, after a very short absence, by having prevailed with the Pope to confer upon him the honour of being publicly and solemnly crowned with laurel in the Capitol.

He set out from Naples to receive this honour, with a preface that he should never return; and arrived at Rome in the beginning of the year 1595, being then about 51 years old: he was met at the entrance of the city by many prelates and persons of distinction, and was introduced by the two cardinals to the Pope, who complimented him by saying, "That his merit would confer as much honour on the laurel he was about to receive, as the laurel had formerly conferred on others." Orders were immediately given to decorate not only the Pope's palace and the Capitol, but all the principal streets through which the procession was to pass: but Tasso, whether from an habitual dejection of mind, or a secret sensation of the first approaches of a disease which he apprehended would be fatal, declared that all these pompous preparations would be in vain.

It happened, that while they were waiting for fair weather to celebrate the solemnity, cardinal Cynthio

fell sick; and, before he was perfectly recovered, Tasso himself was taken ill, and died on the 15th day of his sickness, aged 51. His poems have acquired him an immortal reputation. The principal of them are, 1. *Jerusalem delivered*. 2. *Jerusalem conquered*. 3. *Rinaldo*. 4. *The Seven Days of the Creation*. 5. *The tragedy of Torimond*. 6. *Aminta*, &c. All Tasso's works were printed together at Florence in 1724, in six volumes folio, with the pieces for and against his *Jerusalem delivered*. A pompous edition of this last poem was printed at Venice in 1745, in folio. The best edition of Mirebaud's French translation is that of Paris in 1735, in two volumes duodecimo. His *Aminta* and *Jerusalem liberata*, have been translated into English.

TASSEL, a sort of pendant ornament at the corners of a cushion or the like.—In building, tassels denote those pieces of board that lie under the ends of the mantel-trees.

TASTE, in physiology, a peculiar sensation excited by means of the organs of taste, viz. the papillae on the tongue. See ANATOMY, n° 403.

Intellectual TASTE. See MORALS, n° 179—183.

The external sense with which nature has furnished us, and by which we distinguish and relish the various kinds of nourishment that are adapted to health and pleasure, has in all languages given occasion to the metaphorical word *taste*, by which we express our perception of beauty, deformity, or defect, in the several arts. Taste then, in general, is a quick discernment, a sudden perception, which, like the sensation of the palate, anticipates reflection; like the palate, it relishes what is good with an exquisite and voluptuous sensibility, and rejects the contrary with loathing and disgust; like the palate also, it is often doubtful, and, as it were, bewildered, not knowing whether it should relish or reject certain objects, and frequently requires the influence of habit to give it a fixed and uniform determination.

To have a taste, supposes something more than merely to perceive, and to discern with accuracy the beauty of any work or object. This beauty must be felt, as well as perceived; the mind must be touched and affected by it in a lively and sensible manner. This feeling however, in order to constitute true taste, must not be a vague and confused sensation; but must be attended with a distinct view, a quick and comprehensive discernment of the various qualities, in their several relations and connections, which enter into the composition of the object we contemplate. And in this we see another striking resemblance between the intellectual taste and the sensual one: for as a nice palate perceives immediately the mixture of different wines, so the man of taste will quickly discern the motley mixture of different styles in the same production; and, let the beauties and defects be ever so closely blended in an object, will always be capable of distinguishing the former from the latter.

As the corruption of the sensual taste discovers itself by a relish for only those delicate and high-seasoned dishes, in which all the refinements of art have been employed to excite a forced sensation of pleasure; so the depravity of the intellectual taste manifests itself by an attachment to far-fetched and studied ornaments, and by a want of relish for those beauties which

Tassel,
Taste.

Taste. which are unaffected and natural. The corruption of the sensual taste, which makes us delight in such aliments as are disgusting to those whose organs are in a good state, is in reality a kind of disease; nor is that depravity of the intellectual taste which makes many prefer the burlesque to the sublime, and the laboured stiffness of art to the beautiful simplicity of nature, less a disease in our mental frame.

The intellectual taste is much more formed by education and culture, than the sensual one: for though the latter may be brought, by habit, to relish what at first excited loathing and disgust; yet it does not seem to have been the intention of nature, that the generality of mankind should acquire by custom and experience those sensations and perceptions which are necessary to their preservation. It is otherwise with the intellectual taste: its formation requires time, instruction, and experience. A young man uninstructed in the arts of music and painting, let his natural sensibility be ever so quick and lively, will not immediately distinguish, in a grand concert of music, the various parts whose connection and relation constitute the essence and charm of the composition; nor will he perceive in a picture the gradations of light and shade, that harmony of colours, that correctness of design, which characterise a finished piece: but in process of time, and also by degrees, he learns both to hear and to see in a more perfect manner. The same uninstructed person will find a variety of emotions arise in his mind the first time he is present at the representation of a fine tragedy: but he will neither perceive the dexterity of the author in maintaining the unities; nor that exquisite art by which the drama is so managed, that no person enters upon the scene nor quits it without an evident reason; nor yet that still more nice and difficult art of making the various subordinate interests terminate and centre in one, which absorbs them all. It is only by the force of habit and reflection that he will distinguish these several objects of taste, and feel delightful sensations from circumstances of which formerly he had little or no idea.

Elegant and able artists may communicate their feelings and their discernment to others, and thus excite taste in a nation, which, without them, had never known its refined pleasures. By frequently contemplating the works of great and eminent masters in the various arts, the powers of nature arise into taste; and we imbibe, as it were, the spirit of these illustrious men, so as to come at length to look at a gallery of paintings with the eyes of a Le Brun, a Poussin, or a Le Sueur; nay, we even read works of learning and genius with a portion of that spirit that appears in their composition.

If, in the first periods of the culture of the arts and sciences, it has sometimes happened, that a whole nation have been unanimous in the praise of authors full of defects, and whom succeeding ages have beheld with indifference, and even with contempt; the reason is, that these authors had natural beauties which were perceived by all, while that just discernment that was necessary to distinguish their numerous defects, and which is less the gift of nature than the result of time, habit, and reflection, was as yet acquired by none. Thus Lucilius, who had been in the highest reputation among the Romans, sunk into oblivion when

Horace arose; and Regnier was universally admired by the French, until Boileau appeared; and if there are several ancient authors who have maintained their credit, notwithstanding the absurdities that are to be found in every page of their writings, it must be the authors of those nations among whom no judicious and correct writer has appeared to open their eyes, like Horace among the Romans, and Boileau among the French.

It is a common saying, that there is no disputing about tastes: and if by the taste here be understood the palate, which loaths certain aliments and relishes others, the maxim is just; because it is needless to dispute about what cannot be corrected, or to attempt reforming the constitution and mechanism of organs merely corporeal. But the maxim is false and pernicious, when applied to that intellectual taste which has for its objects the arts and sciences. As these objects have real charms, so there is in reality a good taste which perceives them, and a bad one which perceives them not; and there are certain methods by which we may often correct those mental defects which produce a depraved taste. But it must be granted, at the same time, that there are certain phlegmatic spirits which nothing can enslave; and also certain distorted intellects which it is impossible to rectify: with such, therefore, it is in vain to dispute about taste, because they have none at all.

In many things taste seems to be of an arbitrary nature, and without any fixed or uniform direction; such as in the choice of dress and equipage, and in every thing that does not come within the circle of the finer arts. In this low sphere it should be distinguished by the name of *fancy*; for it is fancy, rather than taste, that produces such an endless variety of new and contradictory modes.

The taste of a nation may degenerate and become extremely depraved; and it almost always happens, that the period of its perfection is the forerunner of its decline. Artists, through the apprehension of being regarded as mere imitators, strike out into new and uncommon paths, and turn aside from the beautiful simplicity of nature, which their predecessors invariably kept in view. In these efforts there is a certain degree of merit, which arises from industry and emulation, and casts a veil over the defects which accompany their productions. The public, fond of novelty, applauds their invention; but this applause is soon succeeded by satiety and disgust. A new set of artists start up, invent new methods to please a capricious taste, and depart still further from nature than those who first ventured from its paths into the wilds of fancy. Thus the taste of a people degenerates into the grossest corruption. Overwhelmed with new inventions, which succeed and efface each other with incredible rapidity, they scarcely know where they are, and cast back their eager and anxious desires towards the period when true taste reigned under the empire of nature. But they implore its return in vain; that happy period cannot be recalled; it deposits, however, in the custody of certain choice spirits, the sublime pleasures of true taste, which they cherish and enjoy in their little circle, remote from the profane eye of the depraved and capricious multitude.

There are vast countries where taste has not yet

Taste.

been able to penetrate. Such are those uncultivated wastes, where civil society has never been brought to any degree of perfection, where there is little intercourse between the sexes, and where all representations of living creatures in painting and sculpture are severely prohibited by the laws of religion. Nothing renders the mind so narrow, and so little, if we may use that expression, as the want of social intercourse; this confines its faculties, blunts the edge of genius, damps every noble passion, and leaves in a state of languor and inactivity every principle that could contribute to the formation of true taste. Besides, where several of the finer arts are wanting, the rest must necessarily languish and decay, since they are inseparably connected together, and mutually support each other. This is one reason why the Asiatics have never excelled in any of the arts; and hence also it is that true taste has been confined to certain countries in Europe.

TASTES of substances, particularly Vegetables. The ancients, particularly Aristotle, and Theophrastus, enumerate only seven primitive tastes: 1. Sweet. 2. Fat. 3. Acid. 4. Acid. 5. Austerity or harsh. 6. Acerb. 7. Salt, and bitter. These last are by Theophrastus confounded.—To these seven primitive tastes of Aristotle and Theophrastus, Pliny has added the following six, which, however, appear to be rather intermediate steps of those already enumerated, than simple tastes. 8. Agreeable (*suavis*), a mode of sweet. 9. Poignant or tart (*acutus*), a less degree of acid. 10. Bitter (*amarus*), a simple taste, confounded by the Greek naturalist, as was observed above, with a salt taste. 11. Vinous, a composition, according to Pliny, of sweet, agreeable, poignant, and austere. 12. Milky taste, composed of agreeable and fat. 13. Watery, which is almost insipid.

The school of Salerno distinguished nine simple tastes, which they characterized by their different temperaments, as follows. I. Acid, bitter, and alkaline salt: WARM. II. Watery or insipid, sweet, and fat: TEMPERATE. III. Acid, harsh or acerb, and acid salt: COLD. The moderns, by distinguishing austere from acerb, adding some things, and retrenching others, have increased the number of simple tastes to ten; which stand thus opposed to each other.

| | | |
|-----------------------|---------------|-----------------------------|
| I. Insipid or watery, | } of opposite | VI. Acid, or alkaline salt. |
| II. Sweet, | | VII. Acid. |
| III. Fat, | | VIII. Austere. |
| IV. Viscous, | | IX. Acerb. |
| V. Acid, | | X. Bitter. |

Tastes are distinguished by their quantum of force or intensity into steps or degrees, which are likewise, sometimes, by writers on the materia medica, used for expressing the different temperaments of those tastes. Thus the simple taste bitter has been divided into ten degrees; and we say, that the root of turmeric is bitter in the first or lowest degree, the seed of blue clematis in the tenth or highest. In the same manner, as a bitter taste indicates a warm temperament, other degrees or divisions arise from the intensity of warmth in the instances in question; and we say, that one is warm in such a degree, and the other in a different.

Some tastes affect the organ of sensation sooner than others which are of a greater degree of intensity.

Acid and bitter tastes, as vinegar and wormwood, are soon felt, and quickly gone. Acid tastes are not felt so soon, and last longer. Thus the sharpness of the seeds of clematis, although in the tenth degree, is not so quickly perceived as the bitterness of roses, although only in the second degree. Hot tastes are slower in affecting the organ of sense, and last longer than others. Thus the bitterness of the roots of black hellebore, which is in the second degree, is perceived on the slightest contact; but its heat, though in the third or fourth degree, is not felt till after two minutes; in like manner, the bitterness of elecampane although only in the fourth degree, is sooner felt than its heat, which is in the eighth.

The climax or increase which is observed in the sensation or perception of tastes, during its continuance, is different in different objects. The heat of galangal causes, at first, a slight sensation, but it is not till the end of one minute that its greatest force is perceived. Black hellebore does not attain its highest sensation till four minutes after its first contact.

The duration of the greatest force of the sensation is likewise different as the substances differ; thus the heat of black hellebore comes to its greatest intensity and diminishes in one minute; that of the root of garden-cress in the same time; that of the root of asarabacca in two minutes.

The leaves of milfoil, which are bitter in the fourth degree, and warm in the first, lose at first their bitterness, whilst their heat still continues. Acorus, or sweet rush, is hot in the first degree, aromatic in the third, and bitter in the fourth; yet its bitterness is presently extinguished; its heat lasts two minutes, and its aromatic sensation seven or eight. The heat of garden-cress endures seven or eight minutes; the bitterness of elaterium a quarter of an hour; the heat of euphorbium and black hellebore half an hour; the acid sensation occasioned by the root of arum, or cuckoo-pint, often lasts 12 hours. From these familiar examples it appears, that the sensation acquires its greatest force in four or six minutes at most from the time of contact; its duration in its decrease is often 30 or 40 minutes and upwards.

Tastes, considered with relation to the parts which they affect, are either, 1. fixed and local; 2. extend themselves to the parts in the neighbourhood of that which is first affected, without, however, relinquishing their former station; as the bitterness of the dried roots of black hellebore, which spreads from the end of the tongue to its middle; and that of the leaves of elaterium, which spreads from the tip of the tongue to its root; or, 3. are translated from one part to another, as in the roots of gentian, the bitterness of which soon relinquishes the tip of the tongue, the part first affected, and translates itself to the middle.

Sapid bodies affect differently the parts which they touch, as the lips, tongue, palate, throat, and gullet.

The lips are affected more strongly by the heat of the root of white hellebore, than any of the other parts.

The tip of the tongue is affected by most plants; gentian and colocynthis affect chiefly the middle; the leaves of elaterium, the root.

The palate is affected by the root of deadly nightshade; its impression lasts four minutes.

The

The throat is more affected than the other parts by the roots of mercury, asparagus, and jalap.

The œsophagus or gullet is particularly affected with heat by the roots of wormwood; the leaves make no impression of this kind; on which account they are not so stomatic as the roots.

As the taste of the same individual undergoes seeming alterations, according to the perfect or morbid state of the external organ; so different individuals of the same species are liable to real variations from climate, soil, and culture. Apples and pears which grow naturally in the woods, are extremely harsh and acid; wild fucory is bitter; wild lettuce disagreeable; culture renders them all sweet and esculent, and moreover produces such variety in the article of taste, that of 172 distinct kinds of pears, and 200 of apples, enumerated by authors, each kind has a peculiar taste.

All the parts of a plant have not the same taste; in some, the fruit has an acid and agreeable taste, whilst the leaves or roots are bitter and disagreeable; in others, the reverse of this happens. It is for this reason that plants can never be properly arranged by their sensible qualities; the different parts of the same plant possessing different qualities, must necessarily be disjoined and arranged under separate articles.

All plants act either by their smell upon the nerves, by their taste upon the muscular fibres, or by both upon the fluids. Sapid bodies never act upon the nerves, nor odoriferous bodies upon the muscular fibres. The former act upon the fluids and solids, and change the fluids, which are evacuated by both sapid and odoriferous substances.

The virtues and qualities of plants are commonly indicated by their taste, smell, and colour.

Insipid plants, and such as have no smell, have rarely any medicinal virtue.

Sapid and odoriferous plants, on the contrary, always possess very strong powers. In fact, to deprive a plant of its taste and smell is to rob it of its virtue, as is evident from the change effected in the fœcule and extracts of arum, calla, cassida, and elaterium.

Sweet-smelling plants are generally of innocent quality; such as are nauseous, and of a rank heavy disagreeable smell, are noxious.

The plants of the following list are striking examples of the latter. Many muskrooms, elder, herb-christopher, aconite, hellebore, asarabacca, stinking ben trefoil, thorn-apple, tobacco, hen-bane, colocintida, and hounds-tongue.

TATE (Nahum), an English poet, born about the middle of the reign of Charles II. in Ireland, where he received his education. He was made poet-laureat to king William upon the death of Shadwell, and held that place until the reign of George I. whose first birth-day ode he lived to write, and executed it with unusual spirit. He died in the mint in 1716, and was succeeded in the laurel by Mr Eusden. He was the author of nine dramatic performances, a great number of poems, and a version of the Psalms in conjunction with Dr Nicholas Brady.

TATIAN, a writer of the primitive church in the second century. He was born in Assyria, and trained up in the Heathen religion and learning. Coming over to Christianity, he became the disciple of Justin Mar-

tyr, whom he attended to Rome. While Justin lived, he continued steadily orthodox; but after Justin's death he made a schism, and became the author of a new sect, condemning marriage, enjoining abstinence from wine and animal-food, and suffering only water to be used in the holy mysteries; whence his followers were called *Encratites* and *Hydroparastate*. None of his works are now extant but his piece against the Gentiles; or, as it is usually intitled, his *Oration to the Greeks*.

TATIUS (Achilles), a native of Alexandria, was the author of a book on the sphere, which father Petau translated into Latin. There is also attributed to him a Greek romance on the loves of Leucippe and Clitophon, of which Salmassius has given a beautiful edition in Greek and Latin, with notes. Suidas says, that this Achilles Tatius was a Pagan, but that he afterwards embraced the Christian religion, and became bishop. Photius mentions him in his *Bibliotheca*.

TATTOU, a beat of a drum at night to advertise the soldiers to retreat, or repair to their quarters in the garrison, or to their tents in a camp.

TATTOOING, an operation in use among the islanders in the South Sea for marking their bodies with figures of various kinds which they consider as ornamental. It is performed by puncturing the skin, and rubbing a black colour into the wounds. The instrument used somewhat resembles a comb, the teeth of which are repeatedly struck into the skin by means of a small mallet. It is very painful; but the children are forced by their relations to submit to it.

TAVERNIER (John Baptiſt), a famous French traveller, was born in 1605. In the course of 40 years he travelled six times to Turkey, Persia, and the East Indies, and visited all the countries in Europe, travelling mostly on foot. His travels have been frequently reprinted in six vols 12mo. He died on his seventh journey to the east, at Moscow, in 1699.

TAVISTOCK, a town of Devonshire in England, situated on the river Tavey or Tave, W. Long. 4. 26. N. 50. 37. It sends two members to parliament, and gives the title of *marquis* to the noble family of Russell dukes of Bedford.

TAUNTON, a town of Somersetshire in England, situated in W. Long. 3. 10. N. Lat. 51. 6. It is pleasantly seated on the river Thone; is reckoned the best town in the county; and sends two members to parliament.

TAURIS, or TEBRIS, a town of Persia, and capital of Aderbeizan. It was formerly the capital of Persia, and is now the most considerable next to Ispahan; for it contains 15,000 houses, besides many separate shops, and about 200,000 inhabitants. It is about five miles in circumference, and carries on a prodigious trade in cotton, cloth, silks, gold and silver brocades, fine turbans, and shagreen leather. There are 300 caravanseras, and 250 mosques. Some travellers suppose it to be the ancient Ecbatana; but of this there is no certainty. It is seated in a delightful plain, surrounded with mountains, from whence a stream proceeds, which runs through the city. E. Long. 46. 50. N. 38. 28.

TAURUS, a great chain of mountains in Asia, which

Taurus, which begin at the eastern part of Little Carimania, and extend very far into the India. In different places they have different names.

Taurus, in astronomy. See there, n° 206.

TAUTOLOGY, a needless repeating of the same thing in different words.

TAWING, the art of dressing skins in white, so as to be fit for divers manufactures, particularly gloves, &c.

All skins may be tawed; but those chiefly used for this purpose are lambs, sheeps, kid, and goat skins.

The method of tawing is this: Having cleared the skins of wool or hair, by means of lime, they are laid in a large vatt of wood or stone, set on the ground full of water, in which quicklime has been slaked; wherein they are allowed to lie a month or six weeks, according as the weather is more or less hot, or as the skins are required to be more or less soft and pliant.

While they are in the vatt, the water and lime is changed twice, and the skins are taken out and put in again every day: and when they are taken out for the last time, they are laid all night to soak in a running water, to get out the greatest part of the lime; and in the morning are laid together by sixes one upon another, upon the wooden leg, and are scraped stoutly one after another, to get the flesh off from the fleshy side, with a cutting two-handled instrument called a knife; and then they cut off the legs (if they are not cut off before) and other superfluous parts about the extremes. Then they are laid in a vatt or pit with a little water, where they are filled with wooden pebbles for the space of a quarter of an hour; and then the vatt is filled up with water, and they are rinsed in it.

In the next place, they are thrown on a clean pavement to drain, and afterwards cast into a fresh pit of water, out of which they rinse them well, and are laid again on the wooden leg, fix at a time, with the hair-side outmost: over which they rub a kind of whetstone very briskly, to soften and fit them to receive four or five more preparations, given them on the leg both on the flesh-side and the hair-side, with the knife, after the manner above-mentioned.

After this they are put into a pit of water and wheaten-bran, and stirred about in it with wooden poles, till the bran is perceived to stick to them, and then they are left: as they rise of themselves to the top of the water by a kind of fermentation, they are plunged down again to the bottom; and at the same time fire is set to the liquor, which takes as easily as if it were brandy, but goes out the moment the skins are all covered.

They repeat this operation as often as the skins rise above the water; and when they have done rising they take them out, lay them on the wooden leg, the fleshy side outwards, and pass the knife over them to scrape off the bran.

Having thus cleared them of the bran, they lay the skins in a large basket, and load them with huge stones to promote their draining: and when they have drained sufficiently, they give them their feeding, which is performed after the manner following.

For one hundred of large sheep-skins, and for smaller in proportion, they take eight pounds of alum, and three of sea-salt, and melt the whole with water in a vessel over the fire, pouring the solution out, while

yet lukewarm, into a kind of trough, in which is twenty pounds of the finest wheat-flower, with the yolks of eight dozen of eggs; of all which is formed a kind of paste, a little thicker than children's pap; which, when done, is put into another vessel, to be used in the following manner.

They pour a quantity of hot water into the trough in which the paste was prepared, mixing two spoonfuls of the paste with it; to do which they use a wooden spoon, which contains just as much as is required for a dozen of skins: and when the whole is well diluted, two dozen of the skins are plunged into it; but they take care that the water be not too hot, which would spoil the paste and burn the skins.

After they have lain some time in the trough, they take them out, one after another, with the hand, and stretch them out; this they do twice; and after they have given them all their paste, they put them into tubs, and there full them afresh with wooden pebbles.

Then they put them into a vat, where they are suffered to lie for five or six days, or more; then they take them out in fair weather, and hang them to dry on cords or racks: and the quicker they are dried the better; for if they be too long a-drying, the salt and alum within them are apt to make them rise in a grain, which is an essential fault in this kind of dressing.

When the skins are dry, they are made up into bundles, and just dipt in fair water, and taken out and drained: they are then thrown into an empty tub, and after having lain some time are taken out and trampled under foot.

Then they draw them over a flat iron instrument, the top of which is round like a battledore, and the bottom fixed into a wooden block, to stretch and open them; and having been opened, they are hung in the air upon cords to dry; and being dry, they are opened a second time, by passing them again over the same instrument.

In the last place they are laid on a table, pulled out, and laid smooth, and are then fit for sale.

TAX, (*Taxa* from the Greek *τάξις*, i. e. *ordo, tributum*;) a tribute or imposition laid upon the subject for the support of government. See **REVENUE**.

It is the ancient indisputable privilege and right of the house of commons, that all grants of subsidies or parliamentary aids do begin in their house, and are first bestowed by them; although their grants are not effectual to all intents and purposes until they have the assent of the other two branches of the legislature. See **COMMONS**. The general reason given for this exclusive privilege of the house of commons, is, that the supplies are raised upon the body of the people, and therefore it is proper that they alone should have the right of taxing themselves. This reason would be unanswerable, if the commons taxed none but themselves: but it is notorious, that a very large share of property is in the possession of the house of lords; that this property is equally taxable, and taxed, as the property of the commons; and therefore the commons not being the sole persons taxed, this cannot be the reason of their having the sole right of raising and modelling the supply. The true reason, arising from the spirit of our constitution, seems to be this. The lords being a permanent hereditary body, created at pleasure by the king,

Tawing,
Tax.

king, are supposed more liable to be influenced by the crown, and when once influenced to continue so, than the commons, who are a temporary elective body, freely nominated by the people. It would therefore be extremely dangerous to give the lords any power of framing new taxes for the subject; it is sufficient that they have a power of rejecting, if they think the commons too lavish or improvident in their grants. But so reasonably jealous are the commons of this valuable privilege, that herein they will not suffer the other house to exert any power but that of rejecting. They will not permit the least alteration or amendment to be made by the lords to the mode of taxing the people by a money-bill: under which appellation are included all bills by which money is directed to be raised upon the subject, for any purpose or in any shape whatsoever; either for the exigencies of government, and collected from the kingdom in general, as the land-tax; or for private benefit, and collected in any particular district, as by turnpikes, parish-rates, and the like. Yet Sir Matthew Hale mentions one case, founded on the practice of parliament in the reign of Henry VI. wherein he thinks the lords may alter a money-bill: and that is, if the commons grant a tax, as that of tonnage and poundage, for four years; and the lords alter it to a less time, as for two years; here, he says, the bill need not be sent back to the commons for their concurrence, but may receive the royal assent without farther ceremony; for the alteration of the lords is consistent with the grant of the commons. But such an experiment will hardly be repeated by the lords, under the present improved idea of the privilege of the house of commons; and, in any case where a money-bill is remanded to the commons, all amendments in the mode of taxation are sure to be rejected.

The commons, when they have voted a supply to his majesty, and settled the *quantum* of that supply, usually resolve themselves into what is called a *committee of ways and means*, to consider the ways and means of raising the supply so voted. And in this committee every member (though it is looked upon as the peculiar province of the chancellor of the exchequer) may propose such scheme of taxation as he thinks will be least detrimental to the public. The resolutions of this committee (when approved by a vote of the house) are in general esteemed to be (as it were) final and conclusive. For though the supply cannot be actually raised upon the subject till directed by an act of the whole parliament, yet no man will scruple to advance to the government any quantity of ready cash, on the credit of a bare vote of the house of commons, tho' no law be yet passed to establish it.

The taxes which are raised upon the subject are either annual or perpetual.

I. The usual annual taxes are those upon land and malt. See LAND and MALT.

II. The perpetual are, 1. The customs. 2. The excise-duty. 3. The salt-duty. 4. The post office. 5. The stamp duty. 6. House and window duty. 7. The duty on hackney-coaches and chairs. 8. That on offices and pensions.—See the articles CUSTOMS, EXCISE, SALT, POST, STAMP, HOUSE, HACKNEY, and OFFICES and PENSIONS.

As to the application of all these, see the articles REVENUE, NATIONAL DEBT, FUNDS, and Civil List.

TAXATION. See REVENUE, TAX, and FEODAL SYSTEM.

TAXUS, the YEW-TREE; a genus of the monodelphia order, belonging to the diccia class of plants. There are two species; of which the most remarkable is the *baccata*, or common yew, growing naturally in many places of England and Scotland. It is found here and there in the Highlands, in a truly wild state. At Glenlure, near Glen-Creran, in Upper-Lorn, are the remains of an old wood of it. The place takes its name from the trees which grow in it; for *Glenlure*, in the Gaelic language, is no other than a corruption of *Gleanuir*, i. e. "The valley of yew-trees."

It is an evergreen tree, of no great height; but the trunk grows to a large size. Mr Pennant has taken notice of a very remarkable decayed one in Fortingal church-yard, whose remains measured 56 feet and an half in circumference. The leaves are of a dark shining green, linear and acute, divided by a longitudinal nerve, and grow in a double series, opposed to each other, on the same plane. The flowers, both male and female, grow from the axis of the leaves. The berry is red and mucilaginous, of a singular structure, being formed out of the receptacle, which swells and becomes succulent, but does not cover the top of the seed. It has a sweet mawkish taste. The wood is red and veined, very hard and smooth, and much used by turners and cabinet-makers. The tree is very patient of the fiers, and will assume almost any figure. It has generally been supposed to have a poisonous quality. We have repeated accounts of horses and cows that have died by eating it; but whether the yew was the immediate cause of their death, is a matter of some doubt. The berries are certainly not poisonous.

Our ancestors esteemed the wood of this tree as superior to any other for making bows. For this intent it was planted in almost every church-yard, for the convenience and ready use of the several parishioners.

TAY, called by the Romans *Tavus* or *Taus*, the largest river in Scotland. It rises in Braidalbin, on the frontiers of Lorn; and having in the passage of a few miles augmented its stream by the accession of several small rills, spreads itself into a lake called *Loch Dochart*; out of which having run but a little space, it expands itself again. Leaving this second lake, it rolls some miles with a considerable body of water, and then diffuses itself abroad in the spacious Loch Tay; which, reckoning from the sources of the river, is 24 miles in length, though, strictly speaking, the lake is but 13; almost as soon as it issues from hence, it receives the river Lion, coming out of Loch Lion, and running through Glen Lion; which, having travelled in a manner parallel to it, from its source, for the space of 25 miles, at length joins the Tay as it enters Athol, which it next traverses, and, directing its course in a manner due east, receives almost all the waters of that country. Bending then to the south, at the distance of six miles, it reaches Dunkeld; which, in the language of our ancestors, signifies "the hill of hazels," was the very centre of the old Caledonia, and is at present esteemed the heart of the Highlands. The river is very broad here, inasmuch that there is a ferry-boat over it at each end of the town. Declining still to the south-east, with a winding course, for above

Taylor. 12 miles, the Tay receives a large supply of waters from the county of Angus; and then running south-west for eight miles more, is joined in that space by several rivers, the most considerable of which is the Almond. Turning then to the south-east, at the distance of about three miles, this copious river comes with a swelling stream to Perth, or St Johnston's, which is the capital of the shire of that name.

The Tay, continuing still a south east course, receives, a few miles below Perth, the river Erne; which, issuing from a loch of the same name, traverses the county of Strathern, and passes by Abernethy, once the capital of the Pictish kingdom: swelled by the waters of this last river, the Tay, running next directly east, enlarges itself till it becomes about three miles broad; but contracts again before the town of Dundee; soon after which it opens into the German ocean. At the entrance of the frith, there are sands both on the north and on the south side, the former styled *Goa*, latter *Aberlay* and *Drunlan*; and before these, in the very mouth of the frith, those which are called the *Cress Sands*. At Buttouness, which is the northern promontory, there are two light-houses. The space between the north and the south sands may be near a mile, with about three fathoms water; but being within the frith, it grows deeper, and in the road of Dundee is full six fathoms. The frith of Tay is not indeed so large or so commodious as that of Forth, but from Buttouness to Perth it is not less than 40 miles; and the whole may be, without any great impropriety, be styled a harbour, which has five on one side, and the shires of Perth and Angus on the other, both very fertile and pleasant countries.

TAYLOR (Dr Jeremy), bishop of Down and Connor in Ireland, was the son of a barber at Cambridge, and there had his education. Upon entering into orders, he became divinity-lecturer of St Paul's in London; and was, by the interest of archbishop Laud, elected fellow of All-souls college, Cambridge, in 1636. Two years after he became one of the chaplains of the archbishop, who bestowed on him the rectory of Uppingham in Rutlandshire. In 1642, he was chaplain to the king; and a frequent preacher before him and the court at Oxford. He afterward attended in the king's army in the condition of a chaplain. Upon the declining of his majesty's cause, he retired into Wales, where he was permitted to officiate as minister, and to keep a school, in order to maintain himself and his children. In this retirement he wrote several of his works. Having spent several years there, his family was visited with sickness; and he lost three sons of great hopes, within the space of two or three months. This affliction touched him so sensibly, that it made him desirous to leave the country; and, going to London, he for a time officiated in a private congregation of loyalists to his great hazard. At length meeting with Edward lord Conway, that nobleman carried him over with him into Ireland, and settled him at Portmore, where he wrote his *Ductor Dubitantium*. Upon the restoration he returned to England: soon after, he was advanced to the bishopric of Down and Connor in Ireland; and had the administration of the see of Dromore granted to him. He was likewise made privy-counsellor, and vice-chancellor of the university of Dublin, which place he held

till his death. He died of a fever at Lisnegary in 1667, and was interred in a chapel of his own erecting on the ruins of the old cathedral of Dromore.

TAYLOR (Dr John), a learned dissenting minister, born in Lancashire. He settled first at Kirkstead in Lincolnshire, where he preached to a small congregation and taught a grammar-school for near 20 years. Afterward he removed to Norwich, where he preached many years in great repute, until he was invited to superintend the academy formed at Warrington in Lancashire: but a few idle differences on formal punctilios and uncertain doctrines kindled into such a flame there, as subjected him to much scurrility and ill treatment, and endangered the very being of the academy. He died in 1761; and among several other judicious performances, his Hebrew and English Concordance, 2 vols. folio, will remain a monument of his critical skill and indefatigable industry.

TAYLOR-BIRD. See MOTACILLA.

TEA, or THEA, the *Tea-plant*; a genus of the monogynia order, belonging to the polyandria class of plants.

This shrub, formerly described by Dr Breynius, in his Century of Exotic Plants, published at Dantzick in 1678, is of a very slow growth, and diminutive size. It has a black, woody, irregularly branched root. The rising stem soon spreads into many irregular branches and twigs. These at the lower end and near the ground often seem to be more in number than they really are; for several seeds being put together in one hole, it frequently happens that two, three, or more shrubs grow up together, and so close to one another, as to be easily mistaken for one, by ignorant or less attentive observers. The bark is dry, thin, weak, chestnut-coloured, firm, and adheres closely to the wood. It is covered with a very thin skin; which being removed, the bark appears, of a greenish colour, a bitter, nauseous, and astringent taste, with a smell much like the leaves of the hazel-nut tree, only more disagreeable and offensive. The wood is hard, fibrous, of a greenish colour, inclining to white, and of a very offensive smell when green. The pith is very small, and adheres close to the wood. The branches and twigs are slender, of different sizes, irregularly beset with simple leaves, standing on very small, fat, green footstalks; and resembling, when full grown, the leaves of the garden cherry-tree; but when young, tender, and gathered for use, those of the common spindle-tree, the colour only excepted. The leaves are smooth on both sides, closely and unequally sawed on the edge, of a dirty dark green colour, which is somewhat lighter on the back, where the nerves being raised considerably, leave so many hollows or furrows on the opposite side. They have one very conspicuous nerve in the middle, which is branched out on each side into five, six, or seven thin transverse ribs, of different lengths, and bent backwards near the edges of the leaves; between these transverse ribs, run a number of small veins. The leaves when fresh have no smell at all; and though astringent and bitterish, as we observed above, are not nauseous, as the bark. They differ very much in substance, size, and shape, according to their age and the situation and nature of the soil in which the shrub is planted. From the wings of the leaves come forth the flowers in autumn. These

Taylor,
Tca.

con-

Tea.

continue to grow till late in winter; and are composed of six petals, one or two of which are generally shrunk, and fall far short of the largeness and beauty of the others. The footstalk of the flower is about half an inch long, and ends in six very small green leaves, which serve instead of the calix or flower-cup. This description, applied by Kämpfer to the shrub, which, as he pretends, produces all the different sorts or preparations of tea, corresponds, says Linnæus, to a particular species only, termed by him *bohea*; for some tea-plants, he observes after Dr Hill, produce flowers composed of nine petals, which must therefore constitute a distinct species from such as have only six. From this circumstance is constructed the other species of that author, *thea viridis*, or green-tea, the flowers of which have always nine petals. The leaves also are much larger than those of the *bohea*, and of a brighter green.

To proceed in our description. Within the petals, which are of a very unpleasant bitterish taste, are placed many white stamina, exceeding small, as in the wild rose, with yellow heads, in shape not unlike a heart. Kämpfer reckoned in one flower 230 of these stamina. To the flowers succeed the fruits in great plenty; these are composed of one, two, but most commonly of three, capsules, of the bigness of wild-plums, adhering like the seed-vessels of the palma christi, to one common footstalk as to a centre, but divided into three pretty deep partitions. Each capsule contains a husk, nut, and seed. The kernel or seed is reddish, of a firm substance like silberds, contains a great quantity of oil, and is very apt to grow rank, which is the reason why there are scarce two in ten that will germinate when sown. The natives make no manner of use of either the flowers or kernels.

The shrub must be, at least, of three years growth before the leaves, which it then bears in plenty, are fit to be plucked. In seven years time, or thereabouts, it rises to a man's height; but as it then grows slowly, and bears but few leaves, the natives generally cut it down quite to the stem, after having first gathered what few leaves it produced. The next year, out of the remaining stem, proceed many young twigs and branches, which bear such abundance of leaves, as will sufficiently compensate for the loss of the former shrub. Some defer the operation of cutting down to the stem till the shrub is of ten years growth.

The leaves must not be tore off by handfuls, but plucked carefully, one by one; and are not to be gathered all at once, but at different times. Those who pluck their shrubs thrice a-year, begin their first gathering about the end of February. The shrub then bears but a few leaves, which are very tender and young, and not yet fully opened, as being scarce above two or three days growth. These small and tender leaves are reckoned much better than the rest, and, because of their scarcity and price, are disposed of only to princes and rich people; for which reason they are called *Imperial-tea*, and by some the *flower of tea*. The second gathering, and the first of those who gather but twice a-year, is made about the latter end of March or beginning of April: some of the leaves are then already come to perfection, others are but half-grown: both, however, are plucked off promiscuously;

Tea.

though care is afterwards taken, previous to the usual preparation, to arrange them into classes, according to their size and goodness. The third and last gathering, which is also the most plentiful, is made in the end of May, when the leaves have attained their full growth, both in number and size. The leaves of this gathering are arranged in like manner as the former, according to their size and goodness, into different classes, the lowest of which contains the coarsest leaves of all, being full two months growth, and that sort which is commonly drank by the vulgar.

The preparation of the leaves consists in drying or roasting them when fresh gathered, over the fire in an iron pan, and rolling them when hot with the palm of the hand on a mat till they become curled. The particulars of this preparation, as related by the ingenious author from whom this description is extracted, are much too tedious for our purpose. The reader is therefore referred to the work itself. Vide Kämpfer's History of Japan, vol. ii. appendix 1.

The tea, after having undergone a sufficient roasting and curling, must, when cold, be put up and carefully kept from the air. In this, indeed, the whole art of preserving it chiefly consists; because the air, in those hot climates, dissipates its extremely subtle and volatile parts much sooner than it would in our colder European countries. The Chinese put it up in boxes of a coarse tin, which, if they be very large, are enclosed in wooden cases of fir, all the clefts being first carefully stopped both within and without. After this manner also it is sent abroad into foreign countries. The Japanese keep their stock of the common tea in large earthen pots, with a narrow mouth. The better sort of tea, namely, that which the emperor himself and the great men make use of, is kept in porcelain pots or vessels, which are supposed to improve its virtues. The coarse tea of the third gathering is not so easily injured by the air as the other sorts; for tho' its virtues are comparatively fewer and less sensible, yet are they more constant and fixed. The country people keep it, as well as the other sorts which they use, in straw-baskets, made like barrels, which they put under the roofs of their houses, near the hole which lets out the smoke; being of opinion that nothing is better than smoke to preserve the virtues of the leaves, and even improve them. Some put it up with common mugwort flowers, or the young leaves of a plant called *sajanqua*, which they believe renders it much more agreeable. Other odorous and aromatic substances are found, upon trial, to produce no such beneficial effect.

The tea, as it is taken inwardly, is prepared in two different ways. The first used by the Chinese, and now all over Europe, is nothing else but a simple infusion of the leaves in hot water. The other way, which is peculiar to the Japanese, is by grinding. In this preparation, the leaves are, by means of a hand-mill made of a black-greenish stone called *serpentine stone*, reduced into a fine delicate powder, which being mixed with hot water into a thin pulp is afterwards sipped. This tea is called *thick tea*, to distinguish it from the simple infusion, and is drank every day by all the rich people and great men in Japan.

The narcotic quality of the fresh unprepared leaves of tea, mentioned above, is destroyed in a great measure.

sure by a repeated and gradual roasting. This operation renders it exhilarating, refreshing, and cleansing. Kæmpfer observes, that tea is particularly serviceable in washing away that tartarous matter which is the efficient cause of calculus concretions, nephritic and gouty distempers; and affirms, that among the great tea-drinkers of Japan, he never met with any who were troubled with the gout or stone.

The leaves of tea, say writers on the *Materia Medica*, are much more used for pleasure than as medicine: the Bohea, however, is esteemed softening, nourishing, and proper in all inward decays; the green is diuretic, carries an agreeable roughness with it into the stomach, which gently astringes the fibres, and gives them such a tenuity as is necessary for a good digestion. Improper or excessive use may no doubt render this or any thing else prejudicial; but, in general, there are very few herbs employed, either in food or medicine, which, used with moderation, are better, pleasanter, or safer, than tea.

We do not find that the tea-plant grows naturally beyond the 35th degree of north latitude on the one hand, and the 45th degree on the other.

TEA-Tree of New Zealand, is a species of myrtle, of which an infusion was drank by Captain Cook's people in their voyages round the world. Its leaves were finely aromatic, astringent, and had a particular pleasant flavour at the first infusion; but this went off at the next filling up of the tea-pot, and a great degree of bitterness was then extracted; for which reason it was never suffered to be twice infused. In a fine soil in thick forests this tree grows to a considerable size; sometimes 30 or 40 feet in height, and one foot in diameter. On a hilly and dry exposure, it degenerates into a shrub of five or six inches; but its usual size is about eight or ten feet high, and three inches in diameter. In that case its stem is irregular and unequal, dividing very soon into branches which rise at acute angles; and only bear leaves and flowers at top. The flowers are white, and very ornamental to the whole plant.

TEAL, in ornithology. See ANAS.

TEARS, a lymph or aqueous humour, which is subtle, limpid, and a little saltish: it is separated from the arterial blood by the lachrymal glands and small glandulous grains on the inside of the eyelids.

TEBETH, the tenth month of the Jewish ecclesiastical year, and fourth of the civil. It answers to our month of December.

TECKLENBURG, a town of Germany, in the circle of Westphalia, capital of a county of the same name, with a castle built on a hill. It was bought by the king of Prussia in 1707. E. Long. 8. 7. N. Lat. 52. 20.

TECHNICAL, expresses somewhat relating to arts or sciences: in this sense we say technical terms. It is also particularly applied to a kind of verses wherein are contained the rules or precepts of any art, thus digested to help the memory to retain them; an example whereof may be seen in the article MIS-
MORRY.

TE DEUM, the name of a celebrated hymn, used in the Christian church, and so called because it begins with these words, *Te Deum laudamus*, We praise thee,

O God. It is sung in the Romish church, with great pomp and solemnity, upon the gaining of a victory, or other happy event.

TEES, a river which rises on the confines of Cumberland, and running eastward divides the county of Durham from Yorkshire, and falls into the German sea below Stockton.

TEETH. See ANATOMY, n° 26.

TEETHING in Children. See MEDICINE, p. 4867.

TEFLIS, the capital of Persian Georgia in Asia, situated on the river Kur or Cyrus, in E. Long. 47. 20. N. Lat. 43°. It is not large; but, according to Sir John Chardin, one of the finest cities in the east, with strong walls on all sides, except on the east, where it is covered by the river Kur. On the south side of it stands a large castle or fortress, built by the Turks in 1576, when they made themselves masters of the city and country, under the command of the famed Mustapha Pacha. The city is very populous, and a place of great trade, especially in furs, which are conveyed hence to Constantinople by the way of Erzerum. As for the silks of this country, they are bought up on the spot by the Armenians, and conveyed to Smyrna and other ports of the Mediterranean; but the greatest part is first sent to Erzerum to be manufactured, the Georgians being very ignorant and unskilful in that respect. From hence, likewise, great quantities of a root called *boya*, is sent to Erzerum and Indolfin, for the use of the linen dyers. There are some magnificent caravanseras, bazars, and palaces, in the city. Of the last, those of the viceroys of Carthuel and Caket are the chief. They reckon no less than 14 churches in the city; one half of them belonging to the Georgians, and the other to the Armenians. As for mosques, the Georgians, it is said, have never suffered any to be built, tho' they are under a Mohammedan government; but have always risen up in arms as often as any attempts have been made to erect such, and destroyed them. Here are some Romish Capuchins, as missionaries; but they go under the denomination of physicians, surgeons, or chemists, which three professions are in great esteem in the east. The great cures they make, and the small fees they take, which are generally in wine, meal, cattle, or young slaves, procure them some esteem, though they are often exposed to the insults of the people, especially when they attempt to make any proselytes to their church. The inhabitants of Teflis are computed at near 20,000; viz. 4000 Armenians, 3000 Mohammedans, 2000 Georgians, and about 500 Romish Armenians, who are much hated by the others: the rest are Persians or strangers, that are continually coming and going.

TEGUMENT, any thing that surrounds or covers another.

TEINTS, and SEMI-TEINTS, in painting, denote the several colours used in a picture, considered as more or less high, bright, deep, thin, or weakened and diminished, &c. to give the proper relieve, softness, or distance, &c. of the several objects.

TELESCOPE, an instrument formed by a combination of optical glasses or metallic speculums with lenses, by which distant objects may be viewed distinctly. See (Index subjoined) OPTICS.

TELL (William,) an illustrious Swiss patriot, chief
in-

Teller,
Tempe.

instrument of the revolution which delivered the Swiss Cantons from the German yoke in 1307. Griser, the governor of these provinces for the emperor Albert, having ordered him, under pain of death, to shoot at an apple placed on the head of one his children, he had the dexterity, though the distance was very considerable, to strike it off without hitting the child. The tyrant, perceiving he had another arrow concealed under his cloak, asked him for what purpose? To which he boldly replied, "To have shot you thro' the heart, if I had had the misfortune to kill my son." The enraged governor now ordered him to be hanged; but his fellow-citizens, animated by his fortitude and patriotism, flew to arms; attacked and vanquished Griser, who was shot to death by Tell; and the association for the independency took place that instant.

TELLER, an officer of the exchequer, in ancient records called *tallier*. There are four of these officers, whose duty is to receive all sums due to the king, and to give the clerk of the pells a bill to charge him therewith. They likewise pay all money due from the king, by warrant from the auditor of the receipt; and make weekly and yearly books both of their receipts and payments, which they deliver to the lord treasurer.

TEMPE, (anc. geog.), a most pleasant place or valley of Theffaly. That there it was, appears from the epithets *Theffalica*, (Livy); *Theffala*, (Ovid); but in what particular district is the question. From the Phthiotica of Catullus, it should seem to be of Phthiotis; but the Peneus, which ran through Tempe, was at too great a distance, being separated from it by Mount Othrys and others. First, however, we shall define Tempe, previous to the determining the particular district in which it lay. The Peneus, according to Pliny, running down between Ossa to the south and Olympus to the north, for 500 stadia, is for half that space navigable: in the direction of this course lies what is called *Tempe*, extending in length for five miles, in breadth for almost an acre and an half, with gentle convexities rising on the right and left, beyond ken of human sight. Within glides the Peneus in its verdant light, green in its pebbles, charming in the grass on its banks, harmoniously vocal with the music of birds. In this description Strabo and Ælian agree; the last adding, that it has an agreeable variety of places of retreat; and that it is not the work of man's hand, but the spontaneous production of nature; and Strabo, that formerly the Peneus formed a lake in this spot, being checked in its course by the higher grounds about the sea; but that an opening being made by an earthquake, and Mount Ossa torn from Olympus, the Peneus gained a free course between them. But Livy, who calls Tempe a grove, remarks a degree of horror rather than amenity, with which the Roman army was struck in marching over the narrow pass; for, besides the desire, difficult to go over, which runs on for five miles, there are steep rocks on each hand, down which the prospect is apt to cause a dizziness heightened by the noise and depth of the interfluent Peneus. Hence it appears that Tempe was in the Pelasgiotis, whose extremity was formerly the Peneus, but afterwards, as is probable, allotted to Magnesia; and thus Pliny places the mouth of the Peneus not in Theffaly itself,

VOL. X.

but in the Magnesia of Theffaly. The name is properly *Temenos*, a sacred grove; whence the Romans formed *Tempus*, and the diminutive *Templum*, or *Templum*. The name *Tempe* became at length an appellative to denote any pleasant spot.

TEMPERAMENT, among physicians, the same with constitution, or a certain disposition of the solids and fluids of the human body, by which it may be properly denominated strong, weak, lax, &c.

In every person there are appearances of a temperament peculiar to himself, tho' the ancients only took notice of four, and some have imagined these were deduced from the theories of the four humours or four cardinal qualities; but it is more probable that they were first founded on observation, and afterwards adapted to those theories, since we find that they have a real existence, and are capable of receiving an explanation. The two that are most distinctly marked, are the sanguineous and melancholic, viz. the temperaments of youth and age.

1. *Sanguineous*. Here there is laxity of solids, discoverable by the softness of hair and succulency; large system of arteries, redundancy of fluids, florid complexion; sensibility of the nervous power, especially to pleasing objects; irritability from the plethora; mobility and levity from lax solids. These characters are distinctly marked, and are proved by the diseases incident to this age, as hæmorrhagies, fevers, &c. but these, as they proceed from a lax system, are more easily cured.

2. *Melancholic Habit*. Here greater rigidity of solids occurs, discoverable by the hardness and crispature of the hair; small proportion of the fluids, hence dryness and leanness; small arteries, hence pale colour; venous plethora, hence turgescency of these, and lividity; sensibility, frequently exquisite, but with great accuracy; moderate irritability, with remarkable tenacity of impressions; steadiness in action and slowness of motion, with great strength; for excess of this constitution in maniacs gives the most extraordinary instance of human strength we know. This temperament is most distinctly marked in old age, and in males. The sanguineous temperament of youth makes us not distinguish the melancholic till the decline of life, when it is very evident, from diseases of the veins, hæmorrhoids, apoplexy, cachexy, obstructions of the viscera, particularly of the liver, dropsies, affections of the alimentary canal, chiefly from slower and weaker influence of the nervous power. So much for the sanguineous and melancholic temperaments; the other two are not so easily explained.—The choleric temperament takes place between youth and manhood. In the

3. *Choleric*, the distribution of the fluids is more exactly balanced; there is less sensibility, and less obesity, with more irritability, proceeding from greater tension, less mobility and levity; and more steadiness in the strength of the nervous power. As to the

4. *Phlegmatic*: This temperament cannot be distinguished by any characters of age or sex. It agrees with the sanguineous in laxity and succulency. It differs from that temperament, and the melancholic, by the more exact distribution of the fluids. Again, it differs from the sanguineous, by having less sensibility, irritability, mobility, and perhaps strength, tho' some-

ment.

Tempera-

ment

Templars.

sometimes indeed this last is found to be great.

These are the ancient temperaments. The temperaments, indeed, are much more various; and very far from being easily marked and reduced to their genera and species, not only on account of variety of temperaments themselves, but also on account of idiosyncrasy.

TEMPERAMENT, in music, is defined by Rousseau to be an operation, which, by means of a slight alteration in the intervals, causes the difference between two contiguous sounds to disappear, makes each of these sounds seem identical with the other, which, without offending the ear, may still preserve their respective intervals or distances one from the other. By this operation, the scale is rendered more simple, and the number of sounds which would otherwise be necessary retrenched. Had not the scale been thus modified, instead of twelve sounds alone which are contained in the octave, more than 60 would be indispensably required to form what we properly call *modulation* in every tone.

It is proved by computation, that upon the organ, the harpsichord, and every other instrument with keys, there is not, and there scarcely can be, any chords properly in tune, save the octave alone. The cause is this, that though three thirds major, or four thirds minor, ought to form a just octave, those are found to surpass, and these not to reach it.

TEMPERING, in the mechanic arts, the preparing of steel and iron, so as to render them more compact, hard, and firm; or even more soft and pliant, according to the respective occasions. See IRON and STEEL.

TEMPLARS, or TEMPLERS, a religious order instituted at Jerusalem about the year 1118. Some religious gentlemen put themselves under the government of the patriarch of Jerusalem, renounced property, made the vow of celibacy and obedience, and lived like canons regular. King Baldwin assigned them an apartment in his palace. They had likewise lands given them by the king, the patriarch, and the nobility, for their maintenance. At first there were but nine of this order, and the two principal persons were Hugo de Paganis and Geoffry of St Omers. About nine years after their institution, a rule was drawn up for them, and a white habit assigned them, by Pope Honorius II. About 20 years afterwards, in the popedom of Eugenius III. they had red crosses sewed upon their cloaks as a mark of distinction; and in a short time they were increased to about 300 in their convent at Jerusalem. They took the name of *Knights Templars*, because their first house stood near the temple dedicated to our Saviour at Jerusalem. This order, after having performed many great exploits against the infidels, became rich and powerful all over Europe; but the knights, abusing their wealth and credit, fell into great disorders and irregularities. Many crimes and enormities being alleged against them, they were persecuted in France, Italy, and Spain; and at last the Pope, by his bull of the 22d of May 1312, given in the council of Vienna, pronounced the extinction of the order of Templars, and united their estates to the order of St John of Jerusalem.

TEMPLE, a general name for places of public worship, whether Pagan, Christian, or otherwise. But the word, in a restrained sense, is used to denote the places or edifices in which the Pagans offered sacrifice to their false gods. The word is formed from the Latin *templum*, which some derive from the Greek *temnos* $\tau\epsilon\mu\nu\sigma$, signifying the same thing; and others from *temno* $\tau\epsilon\mu\nu\omega$, *abscondo*, "I cut off, I separate," in regard a temple is a place separated from common use. Others derive it from the old Latin word *templare*, "to contemplate." It is certain, the ancient augurs gave the name *templa* to those parts of the heavens which they marked out for the observation of the flight of birds.—Their formula was this: *Templa tesqua juncto*. See AUGUR.

TEMPLES, among us, denote two inns of court in London, thus called, because anciently the dwelling-house of the knights-templars. At the suppression of that order, they were purchased by the professors of the common law, and converted into *hospitia* or inns. They are called the *inner* and *middle temple*, in relation to Essex-house; which was also a part of the house of the templars, and called the *outer temple*, because situate without Temple-Bar. In the middle temple, during the time of the templars, the king's treasure was kept: as was also that of the kings of France in the house of templars at Paris. The chief officer was the master of the temple, who was summoned to parliament in 47 Hen. III. and from him the chief minister of the temple-church is still called *master of the temple*.

TEMPLES, in anatomy, a double part of the head, reaching from the forehead and eyes to the two ears. The temples are chiefly formed of two bones called *os temporis*. These parts, according to physicians, were called *tempora*, from their showing the age or time of man by the colour of the hair, which turns white in this part before any other; which Homer seems to have been aware of, by his calling men *poliocrotaphi*, *q. d.* "grey-templed."

TEMPLE (Sir William), grandson of Sir William Temple secretary to the famous earl of Essex in queen Elizabeth's time, who was a younger son of the ancient Temples of Temple-Hall in Leicestershire, was born about 1629. From his youth he discovered a solid penetrating genius, and a wonderful desire of knowledge, which his father Sir John took care to cultivate by all the advantages of a liberal education. His political principles would not suffer him to enter upon any public affairs till the way was made open for the king's reformation in 1660. He then made a distinguished figure at court; and was sent on several embassies, particularly in 1668 to the States-General, when he brought about the triple league between England, Holland, and Sweden. He had a great share in the marriage of the prince of Orange with the lady Mary the duke of York's daughter; and was also one of the plenipotentiaries at the peace of Nimeguen in 1678. But the French interest gaining the ascendant at court, he resigned his public employments, and retired into the country, where he lived in retirement, solely employed in study and the cultivation of his gardens. Mr Swift, afterwards dean of St Patrick's, Dublin, lived with Sir William as his amanuensis, and assisted in preparing his works for the press. Sir William

Templum
Temporalities.

liam died toward the end of the year 1700, at Moor-Park near Farnham in Surry, where, according to his express directions in his will, his heart was buried in a silver box under the sun-dial in his garden, opposite to the window from whence he used to contemplate the works of nature. He wrote, 1. Observations upon the United Provinces. 2. *Miscellanea*. 3. *Memoirs*. 4. An introduction to the History of England. 5. Letters on the most important transactions, 3 vols. Mr Boyer tells us, that he was "an accomplished gentleman, a sound politician, a patriot, and a great scholar. And if this great idea should perchance be shaded by some touches of vanity upon *spleen*, the reader will be so candid as to consider, that the greatest, wisest, and the best of men, have still some failings and imperfections which are inseparable from human nature." Sir William Temple had one son, John Temple, Esq; a man of great abilities and accomplishments, who on the revolution was appointed secretary at war by king William: but he had scarcely been a week in office when, on some secret discontent, he took a boat and drowned himself at London Bridge. This gentleman had married mademoiselle Du Pleffis Rombouillet, a French lady, who had by him two daughters, to whom Sir William bequeathed the bulk of his estate; but with this express condition, that they should not marry Frenchmen: "A nation," says Boyer, "to whom Sir William ever bore a general hatred, upon account of their imperiousness and arrogance to foreigners."

TEMPULUM, in antiquity, in general a place sequestered or set apart; from *Temenos*, called in the Æolic dialect *Tempos*. In a stricter sense, places allotted for religious purposes; and in a still stricter, for a space or quarter of the heavens marked out by the augur with his *lituus*; where he carefully observed the motion and singing of the birds, and in what part of this *Templum* they made their appearance. And hence a place walled round, and destined for the worship of any deity, and consecrated by the augurs, was called *Templum Augustum*; and the act itself *inauguration* or *consecration*.

TEMPORAL, a term generally used for secular, as a distinction from ecclesiastical. Thus we say temporal lords, and spiritual or ecclesiastical lords.

TEMPORALITIES of BISHOPS, are the revenues, lands, tenements, and lay-fees, belonging to bishops, as they are barons and lords of parliament.

The custody of the temporalities of bishops forms a branch of the king's ordinary revenues; (see REVENUE.)—These, upon the vacancy of the bishopric, are immediately the right of the king, as a consequence of his prerogative in church-matters; whereby he is considered as the founder of all archbishoprics and bishoprics, to whom during the vacancy they revert. And for the same reason, before the dissolution of abbeyes, the king had the custody of the temporalities of all such abbeyes and priories as were of royal foundation (but not of those founded by subjects), on the death of the abbot or prior. Another reason may also be given why the policy of the law hath vested this custody in the king; because, as the successor is not known, the lands and possessions of the see would be liable to spoil and devaluation if no one had a property therein. Therefore the law has given the king,

not the temporalities themselves, but the custody of the temporalities till such time as a successor is appointed; with power of taking to himself all the intermediate profits, without any account of the successor; and with the right of presenting (which the crown very frequently exercises) to such benefices and other preferments as fall within the time of vacation. This revenue is of so high a nature, that it could not be granted out to a subject, before or even after it accrued: but now, by the statute 15 Edw. III. st. 4. c. 4 & 5. the king may, after the vacancy, lease the temporalities to the dean and chapter; saving to himself all advowsons, escheats, and the like. Our ancient kings, and particularly William Rufus, were not only remarkable for keeping the bishoprics a long time vacant, for the sake of enjoying the temporalities, but also committed horrible wastes on the woods and other parts of the estate; and to crown all, would never, when the fee was filled up, restore to the bishop his temporalities again, unless he purchased them at an exorbitant price. To remedy which, king Hen. I. granted a charter at the beginning of his reign, promising neither to sell, nor let to farm, or take any thing from, the domains of the church, till the successor was installed. And it was made one of the articles of the great charter, that no waste should be committed in the temporalities of bishoprics, neither should the custody of them be sold. The same is ordained by the statute of Westminster the first; and the statute 14 Edw. III. stat. 4. c. 4. (which permits a lease to the dean and chapter) is still more explicit in prohibiting the other exactions. It was also a frequent abuse, that the king would, for trifling or no causes, seize the temporalities of bishops, even during their lives, into his own hands: but this is guarded against by statute 1 Edw. III. st. 2. c. 2.

This revenue of the king, which was formerly very considerable, is now by a customary indulgence almost reduced to nothing: for, at present, as soon as the new bishop is consecrated and confirmed, he usually receives the restitution of his temporalities quite entire and untouched from the king; and then, and not sooner, he has a fee-simple in his bishopric, and may maintain an action for the profits.

TENAILLES, in fortification, are low works made in the ditch before the curtains. There three sorts. The first are the faces of the bastions produced till they meet, but much lower; the second have faces, flanks, and a curtain; and the third have only faces and flanks.

TENANT, one that holds lands or tenements of some lord or landlord, by rent, fealty, &c. See TENURE.

TENCH, in ichthyology. See CYPRINUS.

TENDER, a small ship in the service of men of war, for carrying men, provisions, or any thing else that is necessary.

TENDONS, in anatomy, are white, firm, and tenacious parts, continuous to the muscles, and usually forming their extremities. See ANATOMY, n° 83, c.

TENEbrio, a genus of insects belonging to the order of coleoptera. The last joint of the antennæ is roundish; the breast is somewhat convex, and margined; the head is stretched forward, and the elytra are stiff. There are 33 species, principally distinguish-

Temporalities
Tenebrio.

Tenedos
Teniers.

Teniers
Tenor.

ed by their colour. The larvæ of some live in damp places under ground among rubbish; of others in flour and different kinds of food, where they perform their metamorphosis. The perfect insects are very troublesome in houses; eating bread, meat, &c. They precipitately avoid the light; resorting in troops to dark damp cellars, where putrefaction allures and nourishes them. They are all of a very dark gloomy appearance, from which circumstance they take their name.

TENEDOS (anc. geog.), an island on the coast of Troas, at the distance of 40⁰ from the continent, and 80 in compass; with a cognominal Æolian town, and a temple of Apollo Smintheus. It was no inconsiderable town, as appears from its coins, inscribed *Tenedii*, the people. Its origin is derived from Tennes, or Tene, who being exposed in a coffer or bog by his father Cygnus the Thracian, at the instigation of the mother-in-law, was by fate carried to this island, made king of it, and at length worshipped as a god on account of his virtues. The island was famous for its earthen ware, for which purpose it had an excellent red clay; and hence Bochart would derive the appellation from *tinedom*, a "red clay." *Tenedia securis*, is a proverbial saying to denote severity; from a law there passed, that persons found in the act of adultery should be put to death; a severity executed on the king's son; and therefore, in the coins of Tenedos, on one side are two heads in memorial of the king and his son, and on the reverse an ax, (Aristotle.) This island still retains its ancient name; and is one of the smallest islands of the Archipelago, situated near the coast of Lesser Asia, west of the ruins of Troy. It belongs to the Turks, and is remarkable for producing the best muscadine wine in the Levant. On the eastern side is a pretty large town, seated at the foot of a mountain, with a fine harbour commanded by a castle. E. Long. 27. o. N. Lat. 29. 30.

TENERIFF, the most considerable of the Canary islands, being about 45 miles in length and 20 in breadth, abounding with wine, different sorts of fruit, cattle, and game. It is subject to earthquakes; and in 1704 there happened one that destroyed several towns and many thousand people. It is remarkable for a very high mountain called the *Peak*, which in a clear day may be seen 100 miles off. It was formerly a volcano, and still emits hot sulphureous steams from chinks in different parts. Its height has been computed by Dr Heberden at 15,396 feet, which is but 148 yards less than three miles. On the top is found the natron, or fossil fixed alkali, and likewise some very pure natural sulphur. W. Long. 16. 22. N. Lat. 28. 30.

TENESMUS, in medicine, a name given by medical writers to a complaint which is a continual desire of going to stool, but without any stool being ready to be voided. This is properly no primary disease, but merely a symptomatic one, and differs in degree according to the disease on which it is an attendant.

TENIERS (David) the Elder, a Flemish painter, born at Antwerp in 1582. He received the first rudiments of his art from the famous Rubens, who highly esteemed him for his promising genius, and with great satisfaction examined and commended his designs. From the school of that celebrated painter Teniers went to finish his studies at Rome: he attached him-

self to Adam Elsheimer for six years; and from the instructions of two such incomparable masters, he formed to himself a peculiar style, which his son cultivated so happily afterward as to bring it to the utmost perfection. His pictures were small; and his subjects usually shops, laboratories, humorous conversations, and rural festivities. The demand for his pieces was universal; and even his master Rubens thought them an ornament to his cabinet. He died at Antwerp in 1649.

TENIERS (David) the Younger, also an admirable painter, was the son of the former, and was born at Antwerp in 1610. He obtained the name of *Ape of Painting*, from his imitating the manner of different painters with such exactness, as to deceive even the nicest judges. He improved greatly under his father, and obtained such reputation as introduced him to the favour of the great. The archduke Leopold William made him gentleman of his bed-chamber; and all the pictures of his gallery were copied by Teniers, and engraved by his direction. The king of Spain and Don Juan of Austria set so high a value on his pictures, that they built a gallery on purpose for them. William prince of Orange honoured him with his friendship; and Rubens not only esteemed his works, but assisted him with his advice. His principal talent lay in landscapes adorned with small figures. He also painted men drinking and smoking, chemists laboratories, country fairs, and the like. His small figures are superior to his large ones. He died in 1694.

The works of the father and son are thus distinguished: The latter discover a finer touch and fresher pencil, greater variety of attitudes, and a better disposition of the figures. The father retained something of the tone of Italy in his colouring, which was stronger than the son's; besides, the son used to put at the bottom of his pictures, David Teniers, junior.

Abraham, another son of David the Elder, was equal, if not superior, to his father and brother in the expression of his characters, and his understanding the *claro obscuro*; though he was inferior in the sprightliness of his touch, and the lightness of his pencil.

TENISON (Dr Thomas), archbishop of Canterbury, was born at Cottenham in Cambridgeshire in 1636; and studied at Corpus Christi college in Cambridge. In his youth, while the fanatical government lasted, he applied himself to physic; but afterward went into orders, and was some time minister of St Andrew's church, Cambridge; where he attended the sick during the plague in 1665, which his parishioners acknowledged by the present of a piece of plate. He showed himself very active against the growth of Popery by his writings both in king Charles and king James's reigns: in 1680 he was presented to the vicarage of St Martin's in the Fields, London, to which parish he made several donations; and among others, endowed a free school, and built a handsome library, which he furnished with useful books. King William and queen Mary, in 1689, presented him to the archdeaconry of London; in 1691, he was nominated to the see of Lincoln, and in 1694 he succeeded Dr Tillotson as archbishop of Canterbury. He performed all the duties of a good primate for 20 years, and died in 1715.

TENOR, or TENOUR, the purport or content of a writing or instrument in law, &c.

TENOR

Tenor || Tenthredo. TENOR, in music, the first mean, or middle part, or that which is the ordinary pitch of the voice, when neither raised to a treble nor lowered to a bass.

TENSE, in grammar, an inflection of verbs, whereby they are made to signify or distinguish the circumstance of time in what they affirm. See GRAMMAR.

TENT, in war, a pavilion or portable house. They are made of canvas, for officers and soldiers to lie under when in the field. The sizes of the officers tents are not fixed; some regiments have them of one size, and some of another: a captain's tent and marquee is generally $10\frac{1}{2}$ feet broad, 14 deep, and 8 high: the subalterns are a foot less; the major's and lieutenant-colonel's a foot larger; and the colonel's two feet larger. The subalterns of foot lie two a tent, and those of horse but one. The tents of private men are $6\frac{1}{2}$ feet square, and 5 feet high; and hold five soldiers each. The tents for horse are 7 feet broad, and 9 feet deep: they hold likewise five men and their horse accoutrements.—The word is formed from the Latin *tentorium*, of *tendo*, “I stretch,” in regard tents are usually made of canvas stretched out, and sustained by poles, with cords and pegs.

TENT, in surgery, a roll of lint made into the shape of a nail with a broad flat head, chiefly used in deep wounds and ulcers. They are of service, not only in conveying medicines to the most intimate recesses and sinuses of the wound, but to prevent the lips of the wound from uniting before it is healed from the bottom; and by their assistance grumous blood, fordes, &c. are readily evacuated.

TENTHREDO, the SAW-FLY; a genus of insects belonging to the order of hymenoptera. The mouth is furnished with jaws, but has no proboscis; the wings are plain and tumid; the sting consists of two serrated laminae, and the scutellum of two grains placed at a distance. The species are very numerous, differing from one another in colour and size. They are not very shy. Some, by means of their saw, deposit in the buds of flowers, others on the twigs of trees or shrubs, eggs from which are produced false caterpillars. The implement with which they are armed is nowise formidable; as it appears only destined to the purpose of depositing their eggs.

The sylvatica is a beautiful species. The antennæ are setaceous, and have more than 20 joints. The head is blue; the trunk grey mottled with yellow; the body is black; the lines dividing the rings are brownish; the six terminatory segments are amber-coloured. The wings are brown, with a dusky edge. The legs are yellow. This delicate fly is found in damp woods and moors in August and September. When the female lays her eggs, there goes with them an acrid mucilaginous juice, which perverts the course of the sap in the plant, and makes it grow into a kind of gall; this operates as soon as emitted, and scarifies the part the saw has wounded. One may see bubbles of this soft and clammy juice always left upon the plant; the wound is oblong and crooked, and the part becomes black as if burnt. The egg increases in signification twice its size, or more, after it is lodged in the plant; nor is this strange, since it has no hard covering. The larvæ may easily be known by the number of their feet, which are always more than 16; by which they differ from caterpillars, which have 16 at most, and

never fewer than 8. In order to accomplish their metamorphose, they hide themselves in the ground, spin their cod, the inside of which is lined with a very fine down, and admit through the netted texture that moisture from the earth which they have need of in the state of chrysalids.

TENTHS, and FIRST-FRUIITS of *Spiritual Preferment*, a branch of the king's revenue. See REVENUE.

These were originally a part of the Papal usurpations over the clergy of this kingdom; first introduced by Pandulph the pope's legate, during the reigns of king John and Henry III. in the fee of Norwich; and afterwards attempted to be made universal by the popes Clement V. and John XXII. about the beginning of the 14th century. The first-fruits, *primitie*, or *annates*, were the first year's whole profits of the spiritual preferment, according to a rate or *valor* made under the direction of pope Innocent IV. by Walter bishop of Norwich in 38 Hen. III. and afterwards advanced in value by commission from pope Nicholas III. A. D. 1292, 20 Edw. I.; which valuation of pope Nicholas is still preserved in the exchequer. The tenths, or *decime*, were the tenth part of the annual profit of each living by the same valuation; which was also claimed by the holy see, under no better pretence than a strange misapplication of that precept of the Levitical law, which directs, that the Levites “should offer the tenth part of their tithes as a heave-offering to the Lord, and give it to Aaron the high-priest.” But this claim of the pope met with vigorous resistance from the English parliament; and a variety of acts were passed to prevent and restrain it, particularly the statute 6 Hen. IV. c. 1. which calls it a *horrible mischief and damnable custom*. But the Popish clergy, blindly devoted to the will of a foreign master, still kept it on foot; sometimes more secretly, sometimes more openly and avowedly: so that in the reign of Henry VIII. it was computed, that in the compass of 50 years 800,000 ducats had been sent to Rome for first-fruits only. And as the clergy expressed this willingness to contribute so much of their income to the head of the church, it was thought proper (when in the same reign the papal power was abolished, and the king was declared the head of the church of England) to annex this revenue to the crown; which was done by statute 26 Hen. VIII. c. 3. (confirmed by statute 1 Eliz. c. 4.); and a new *valor beneficiorum* was then made, by which the clergy are at present rated.

By these last-mentioned statutes all vicarages under ten pounds a-year, and all rectories under ten marks, are discharged from the payment of first-fruits: and if, in such livings as continue chargeable with this payment, the incumbent lives but half a year, he shall pay only one quarter of his first-fruits; if but one whole year, then half of them; if a year and a half, three quarters; and if two years, then the whole, and not otherwise. Likewise by the statute 27 Henry VIII. c. 8. no tenths are to be paid for the first year, for then the first-fruits are due: and by other statutes of queen Anne, in the fifth and sixth years of her reign, if a benefice be under 50*l.* *per annum* clear yearly value, it shall be discharged of the payment of first-fruits and tenths.

Thus the richer clergy being, by the criminal bigotry of their Popish predecessors, subjected at first to a foreign

Tenths.

foreign exaction, were afterwards, when that yoke was shaken off, liable to a like misapplication of their revenues, through the rapacious disposition of the then reigning monarch; till at length the piety of queen Anne restored to the church what had been thus indirectly taken from it. This she did, not by remitting the tithes and first-fruits entirely; but, in a spirit of the truest equity, by applying these superfluities of the larger benefices to make up the deficiencies of the smaller. And to this end she granted her royal charter, which was confirmed by the statute 2 Ann. c. 11. whereby all the revenue of first-fruits and tithes is vested in trustees for ever, to form a perpetual fund for the augmentation of poor livings. This is usually called *queen Anne's bounty*; which has been still farther regulated by subsequent statutes.

TENURE, in law, signifies the manner whereby lands or tenements are held, or the service that the tenant owes to his lord.

Of this kingdom almost all the real property is by the policy of our laws supposed to be granted by, dependent upon, and holden of, some superior lord, by and in consideration of certain services to be rendered to the lord by the tenant or possessor of this property. The thing holden is therefore styled a *tenement*, the possessors thereof *tenants*, and the manner of their possession a *tenure*. Thus all the lands in the kingdom is supposed to be holden, mediately or immediately, of the king; who is styled the *lord paramount*, or above all. Such tenants as held under the king immediately, when they granted out portions of the lands to inferior persons, became also lords with respect to those inferior persons, as they were still tenants with respect to the king; and, thus partaking of a middle nature, were called *mesne* or *middle lords*. So that if the king granted a manor to A, and he granted a portion of the land to B, now B was said to hold of A, and A of the king; or, in other words, B held his lands immediately of A, but mediately of the king. The king therefore was styled *lord paramount*; A was both tenant and lord, or was a *mesne lord*; and B was called *tenant paravail*, or the *lowest tenant*, being he who was supposed to make avail, or profit of the land. In this manner are all the lands of the kingdom holden which are in the hands of subjects: for according to Sir Edward Coke, in the law of England we have not properly *allodium*; which we have seen in the name by which the feudists abroad distinguish such estates of the subject as are not holden of any superior. So that at the first glance we may observe, that our lands are either plainly feuds, or partake very strongly of the feudal nature.

All tenures being thus derived, or supposed to be derived, from the king, those that held immediately under him, in right of his crown and dignity, were called his *tenants in capite*, or in *chief*; which was the most honourable species of tenure, but at the same time subjected the tenants to greater and more burdensome services than inferior tenures did. And this distinction ran through all the different sorts of tenure.

There seem to have subsisted among our ancestors four principal species of lay-tenures, to which all other may be reduced: the grand criteria of which were the natures of the several services or renders

that were due to the lords from their tenants. The services, in respect of their quality, were either free or base services; in respect of their quantity and the time of exacting them, were either certain or uncertain. Free services were such as were not unbefitting the character of a soldier or a freeman to perform; as to serve under his lord in the wars, to pay a sum of money, and the like. Base services were such as were fit only for peasants or persons of a servile rank; as to plough the lord's land, to make his hedges, to carry out his dung, or other mean employments. The certain services, whether free or base, were such as were stinted in quantity, and could not be exceeded on any pretence; as, to pay a stated annual rent, or to plough such a field for three days. The uncertain depended upon unknown contingencies: as, to do military service in person, or pay an assessment in lieu of it when called upon; or to wind a horn upon the appearance of invaders; which are free services: or to do whatever the lord should command; which is a base or villain service.

From the various combinations of these services have arisen the four kinds of lay-tenure which subsisted in England till the middle of the last century; and three of which subsist to this day. Of these Bracton (who wrote under Henry the third) seems to give the clearest and most compendious account, of any author ancient or modern, of which the following is the outline or abstract: "Tenements are of two kinds, frank-tenement, and villenage. And, of frank-tenements, some are held freely in consideration of homage and knight-service; others in free-socage, with the service of fealty only. And again, of villenages, some are pure, and others privileged. He that holds in pure villenage shall do whatsoever is commanded him, and always be bound to an uncertain service. The other kind of villenage is called *villain-socage*; and these villain-socmen do villain-services, but such as are certain and determined." Of which the sense seems to be as follows: first, where the service was free, but uncertain, as military service with homage, that tenure was called the *tenure in chivalry*, *per servitium militare*, or by knight-service. Secondly, where the service was not only free, but also certain, as by fealty only, by rent and fealty, &c. that tenure was called *liberum socagium*, or *free socage*. These were the only free holdings or tenements; the others were villenous or servile: as, thirdly, where the service was base in its nature, and uncertain as to time and quantity, the tenure was *purum villenagium*, absolute or pure villenage. Lastly, where the service was base in its nature, but reduced to a certainty, this was still villenage, but distinguished from the other by the name of *privileged villenage*, *villanagium privilegiatum*; or it might be still called *socage* (from the certainty of its services), but degraded by their baseness into the inferior title of *villanum socagium*, villain-socage.

1. The military tenure, or that by knight-service, was done away by stat. 12 Car. II. For an account of this species of tenure, see *FEODAL System*, and *Knight-Service*; and for its incidents, see *AIDS*, *RELIEF*, *PRIMER-SEISIN*, *WARDSHIP*, *MARRIAGE*, *FINES*, and *ESCHEAT* (in *APPENDIX*).

2. The second species of tenure or free-socage, not only subsists to this day, but has in a manner absorbed

Tenure. bed and swallowed up (since the statute of Charles the second) almost every other species of tenure. See SOCAGE.

The other grand division of tenure, mentioned by Bracton is that of villenage, as contradistinguished from *liberum tenementum*, or frank-tenure. And this (we may remember) he subdivides into two classes, pure and privileged villenage: from whence have arisen two other species of our modern tenures.

3. From the tenure of pure villenage have sprung our present copyhold-tenures, or tenure by copy of court-roll at the will of the lord; in order to obtain a clear idea of which it will be previously necessary to consult the articles MANOR and VILLENAGE.

As a farther consequence of what has been there explained, we may collect these two main principles, which are held to be the supporters of a copyhold-tenure, and without which it cannot exist; 1. That the lands be parcel of and situate within that manor under which it is held. 2. That they have been demised, or demisable, by copy of court-roll immemorially. For immemorial custom is the life of all tenures by copy; so that no new copyhold can, strictly speaking, be granted at this day.

In some manors, where the custom hath been to permit the heir to succeed the ancestor in his tenure, the estates are styled *copyholds of inheritance*; in others, where the lords have been more vigilant to maintain their rights, they remain copyholds for life only; for the custom of the manor has in both cases so far superseded the will of the lord, that, provided the services be performed or stipulated for by fealty, he cannot in the first instance refuse to admit the heir of his tenant upon his death; nor, in the second, can he remove his present tenant so long as he lives, though he holds nominally by the precarious tenure of his lord's will.

The fruits and appendages of a copyhold-tenure, that it hath in common with free tenures, are fealty, services (as well in rents as otherwise), reliefs, and escheats. The two latter belong only to copyholds of inheritance; the former to those for life also. But, besides these, copyholds have also heriots, wardship, and fines. Heriots, which are agreed to be a Danish custom, are a render of the best beast or other good (as the custom may be) to the lord on the death of the tenant. This is plainly a relic of villenage-tenure; there being originally less hardship in it, when all the goods and chattels belonged to the lord, and he might have seized them even in the villen's lifetime. These are incident to both species of copyhold; but wardship and fines to those of inheritance only. Wardship, in copyhold-estates, partakes both of that in chivalry and that in focage. Like that in chivalry, the lord is the legal guardian; who usually assigns some relation of the infant tenant to act in his stead: and he, like guardian in focage, is accountable to his ward for the profits. Of fines, some are in the nature of primer-feins, due on the death of each tenant, others are mere fines for alienation of the lands; in some manors, only one of those sorts can be demanded, in some both, and in others neither. They are sometimes arbitrary and at the will of the lord, sometimes fixed by custom: but, even when arbitrary,

the courts of law, in favour of the liberty of copyholders, have tied them down to be reasonable in their extent; otherwise they might amount to dissipation of the estate. No fine therefore is allowed to be taken upon descents and alienations, (unless in particular circumstances) of more than two years improved value of the estate. From this instance we may judge of the favourable disposition that the law of England (which is a law of liberty) hath always shown to this species of tenants, by removing, as far as possible, every real badge of slavery from them, however some nominal ones may continue. It suffered custom very early to get the better of the express terms upon which they held their lands; by declaring, that the will of the lord was to be interpreted by the custom of the manor: and, where no custom has been suffered to grow up to the prejudice of the lord, as in this case of arbitrary fines, the law itself interposes in an equitable method, and will not suffer the lord to extend his power so far as to disinherit the tenant.

4. There is yet a fourth species of tenure, described by Bracton under the name sometimes of *privileged villenage*, and sometimes of *villain-focage*. See *Privileged VILLENAGE*.

Having in the present article and those referred to, taken a compendious view of the principal and fundamental points of the doctrine of tenures, both ancient and modern, we cannot but remark the mutual connection and dependence that all of them have upon each other. And upon the whole it appears, that, whatever changes and alterations these tenures have in process of time undergone, from the Saxon æra to the 12 Car. II. all lay-tenures are now in effect reduced to two species; free-tenure in common focage, and base-tenure by copy of court-roll. But there is still behind one other species of tenure, reserved by the statute of Charles II. which is of a spiritual nature, and called the tenure in *FRANK-ALMOIGN*; see that article.

TEPID, a term used by writers on mineral waters, &c. to express such of them as have a less sensible cold than common water.

TERCERA, one of the largest islands of the Azores, or Western Islands, lying in the Atlantic Ocean. It is about 40 miles in circumference; and surrounded with craggy rocks, which render it almost inaccessible. The soil is fertile, abounding in corn, wine, and fruits; and they have such plenty of cattle, that they supply the ships therewith that call there. However, their principal trade is wood. The inhabitants are lively and well made; and they pretend to a great deal of religion and gallantry at the same time. They pique themselves upon points of honour, and are extremely revengeful. It is their custom to rove about in the night-time in quest of intrigues, and seldom fail in finding women for their purpose. It is subject to Portugal; and Angra is the capital town.

TEREBINTHUS, in botany. See PISTACIA.

TEREDO, the PIERCER; a genus of insects belonging to the order of vermes testacea. There is but one species, viz. the navalis, with a slender bending shell. It inhabits the Indian seas, whence it was imported into the European. It penetrates easily into the stoutest oak-planks, and produces

Tenure
||
Teredo.

produces dreadful destruction to the ships by the holes it makes in their sides; and it is to avoid the effects of this insect that vessels require sheathing.

TERENCE, or PUBLIUS TERENTIUS AFER, a celebrated comic poet of ancient Rome, was born at Carthage in Africa. He was slave to Terentius Lucanus the senator; who gave him his liberty on account of his wit, his good mien, and great abilities. Terence, on his becoming a freed man, applied himself to the writing of comedies; in the execution of which he imitated Menander and the other celebrated comic poets of Greece. Cicero gives him the most pompous eulogiums, both for the purity of his language and the perspicuity and beauty of his compositions, which he considers as the rule and standard of the Latin tongue; and observes, that they were esteemed so fine and elegant, that they were thought to have been written by Scipio and Lelius, who were then the greatest personages and the most eloquent of the Roman people. Terence died while on a voyage into Greece, about the 17th year before the Christian æra. There are six of the comedies extant, of which the best editions are the Elzevir one 1635, 12mo; that *cum integris notis, Donati, et selectis variorum*, 1686, 8vo; Westerhovius's, in two vols 4to 1726; and that of Bentley the same year, 4to. Madam Dacier has given a beautiful French version of this author; and an ingenious and correct English translation was published in 4to, 1768, by Mr Colman.

TERM, in law, is generally taken for a limitation of time or estate; as, a lease for term of life or years.

Term, however, is more particularly used for that time wherein our courts of justice are open; in opposition to which, the rest of the year is called *vacation*.

TERM, in grammar, denotes some word or expression of a language.

TERM in the *Arts*, or TERM of Art, is a word which, besides the literal and popular meaning which it has or may have in common language, bears a further and peculiar meaning in some art or science.

TERMES, a genus of insects belonging to the order of aptera. The antennæ are fetaceous, the mouth armed with jaws; the feet are six, formed for running. There are two species.

1. The fatale, or white ant, of a yellowish colour, is a native of both the Indies; makes its nest of wood, which it draws out into a cylindrical form as it moves along; inhabits dark and shady places, never appearing in the open air. It is in the highest degree pernicious, destroying every thing of wood or cloth, whether of animal or vegetable materials, penetrating into its substance and devouring it, while the surface is left entire. It can only be destroyed by quicklime.

Of the white ants of India and Africa we have a very curious account, published in the 71st volume of the Philosophical Transactions by Mr Henry Smeathman of Clement's Inn. According to this account, the works of these insects surpass those of the bees, wasps, beavers, and another animals, as much at least as those of the most polished European nations excel those of the least cultivated savages. And, even with regard to man, his greatest works, the boasted pyramids, fall comparatively far short, even in size alone,

of the structures raised by these insects. The labourers among them employed in this service are not a quarter of an inch in length; but the structures which they erect rise to 10 or 12 feet and upwards above the surface of the earth. Supposing the height of a man to be six feet, the author calculates, that the buildings of these insects may be considered, relatively to their size and that of a man, as being raised to near five times the height of the greatest of the Egyptian pyramids; that is, corresponding with considerably more than half a mile. We may add, that, with respect to the interior construction, and the various members and dispositions of the parts of the building, they appear greatly to exceed that or any other work of human construction.

The most striking parts of these structures are—the royal apartments, the nurseries, magazines of provisions, arched chambers and galleries, with their various communications; the ranges of Gothic-shaped arches, projected, and not formed by mere excavation, some of which are two or three feet high, but which diminish rapidly, like the arches of aisles in perspectives; the various roads, sloping stair-cases, and bridges, consisting of one vast arch, and constructed to shorten the distance between the several parts of the building; which would otherwise communicate only by winding passages. These astonishing structures are the works of an insect only a quarter of an inch long, and 25 of which weigh only one grain—But these and many other curious instances of the great sagacity and powers of these insects cannot be understood, without viewing the plates in which their feeble frames, and comparatively stupendous works, are delineated.

The œconomy of these industrious insects appears to have been very attentively observed by the ingenious author, as well as their buildings. There are three distinct ranks or orders among them, constituting a well-regulated community. These are, first, the *labourers*, or working insects; next the *soldiers*, or fighting order, who do no kind of labour, and are about twice as long as the former, and equal in bulk to about 15 of them; and lastly, the winged or perfect insects, who may be called the *nobility* or *gentry* of the state; for they neither labour nor fight, being scarcely capable even of self-defence.—“These only are capable of being elected *kings* or *queens*; and nature has so ordered it, that they emigrate within a few weeks after they are elevated to this state, and either establish new kingdoms, or perish within a day or two.”

This last-mentioned order differs so much from the other two, that they have not hitherto been supposed to belong to the same community. In fact, they are not to be discovered in the nest till just before the commencement of the rainy season; when they undergo the last change, which is preparative to the formation of new colonies. They are equal in bulk to two soldiers and about 30 labourers; and are furnished with four wings, with which they are destined to roam about for a few hours; at the end of which time they lose their wings, and become the prey of innumerable birds, reptiles, and insects: while probably not a pair out of many millions of this unhappy race get into a place of safety, fulfil the first law of nature, and lay the

four-

Terms. foundation of a new community. In this state many fall into the neighbouring waters, and are eat with avidity by the Africans. The author found them delicate, nourishing, and wholesome; without sauce or other help from cookery, than merely roasting them in the manner of coffee.

The few fortunate pairs who happen to survive this annual massacre and destruction, are represented by the author as being casually found by some of the labourers, that are continually running about on the surface of the ground, and are elected kings and queens of new states. Those who are not so elected and preserved, certainly perish, and most probably in the course of the following day. By these industrious creatures the king and queen elect are immediately protected from their innumerable enemies, by inclosing them in a chamber of clay; where the business of propagation soon commences. Their "voluntary subjects" then busy themselves in constructing wooden nurseries, or apartments entirely composed of wooden materials, seemingly joined together with gums. In-to these they afterwards carry the eggs produced from the queen; lodging them there as fast as they can obtain them from her. The author even furnishes us with plausible reasons to believe, that they here form a kind of garden for the cultivation of a species of microscopical mushroom; which Mr König (in an essay on the East Indian termites, read before the Society of Naturalists of Berlin) conjectures to be the food of the young insects. But perhaps the most wonderful, and at the same time best authenticated, part of the history of these singular insects is that which relates to the queen or mother of the community, in her pregnant state.

After impregnation, a very extraordinary change begins to take place in her person, or rather in her abdomen only. It gradually increases in bulk, and at length becomes of such an enormous size as to exceed the bulk of the rest of her body 1500 or 2000 times. She becomes 1000 times heavier than her consort; and exceeds 20,000 or 30,000 times the bulk of one of the labourers. In this state, the matrix has a constant peristaltic or undulating motion; the consequence of which is (as the author has counted them) the protrusion of 80,000 eggs in 24 hours.

These eggs, says the author, "are instantly taken from her body by her attendants (of whom there always are, in the royal chamber and the galleries adjacent, a sufficient number in waiting) and carried to the nurseries—which are sometimes four or five feet distant in a straight line.—Here, after they are hatched, the young are attended and provided with every thing necessary, until they are able to shift for themselves, and take their share of the labours of the community."

Many curious and striking particulars are related of the great devastations committed by this powerful community; who construct roads, or rather covered ways, diverging in all directions from the nest, and leading to every object of plunder within their reach. Though the mischiefs they commit are very great, such is the œconomy of nature, that it is probably counterbalanced by the good produced by them; in quickly destroying dead trees and other substances, which, as the author observes, would, by a tedious

decay, serve only to encumber the face of the earth. Such is their alacrity and dispatch in this office, that the total destruction of deserted towns is so effectually accomplished, that in two or three years a thick wood fills the space; and not the least vestige of a house is to be discovered.

From the many singular accounts here given of the police of these insects, we shall select and abridge only one; respecting the different functions of the labourers and soldiers, or the civil and military establishments in this community, on an attempt to examine their nest or city.

On making a breach in any part of the structure with a hoe or pick-axe, a soldier immediately appears, and walks about the breach; as if to see whether the enemy is gone, or to examine whence the attack proceeds. In a short time he is followed by two or three others, and soon afterwards by a numerous body, who rush out as fast as the breach will permit them; their numbers increasing as long as any one continues to batter the building. During this time they are in the most violent bustle and agitation; while some of them are employed in beating with their forceps upon the building, so as to make a noise that may be heard at three or four feet distance. On ceasing to disturb them, the soldiers retire, and are succeeded by the labourers, who hasten in various directions towards the breach; each with a burden of mortar in his mouth, ready tempered. Though there are millions of them, they never stop or embarrass each other; and a wall gradually arises that fills up the chasm. A soldier attends every 600 or 1000 of the labourers, seemingly as a director of the works; for he never touches the mortar, either to lift or carry it. One in particular places himself close to the wall which they are repairing, and frequently makes the noise above-mentioned; which is constantly answered by a loud hiss from all the labourers within the dome: and at every such signal, they evidently redouble their pace, and work as fast again.

The work being completed, a renewal of the attack constantly produces the same effects. The soldiers again rush out, and then retreat, and are followed by the labourers, loaded with mortar, and as active and diligent as before. "Thus," says the author, "the pleasure of seeing them come out to fight or to work alternately may be obtained, as often as curiosity excites or time permits: and it will certainly be found, that the one order never attempts to fight, or the other to work, let the emergency be ever so great." The obstinacy of the soldiers is remarkable. "They fight to the very last, disputing every inch of ground so well as often to drive away the negroes, who are without shoes, and make white people bleed plentifully through their stockings."

Such is the strength of the buildings erected by these puny insects, that when they have been raised to little more than half their height, it is always the practice of the wild bulls to stand as sentinels upon them, while the rest of the herd is ruminating below. When at their full height of 10 or 12 feet, they are used by the Europeans as places to look out from, over the top of the grass, which here grows to the height of 13 feet upon an average. The author has stood with four men on the top of one of these build-

Terms.

Terminalia ings, in order to get a view of any vessel that might come in sight.

Terpander.

2. The *pullatorium*, or death-watch, varies in colour and size; being sometimes quite white or grey, at others of a lead colour. In some the abdomen is marked with a brown annular band, after which, near the tail, is found a brown spot. The insect is commonly found in old wood, decayed tables, or books not often looked into. It runs and even leaps a little when touched. Those met with in houses are whiter than those which may be seen in gardens and in the fields, on walls, and the trunks of trees, which are more of a brown colour, and somewhat hairy. This insect imitates the ticking of a watch, which some imagine it does by striking its head against the wainscot; and hence Linnæus has given it the name of *pullatorium*. But this noise is occasioned by one of the *ptini*, and is an amorous invitation. By superstitious people it is thought to be a prognostic of death.

TERMINALIA, in antiquity, seals celebrated by the Romans in honour of the god *Terminus*†.

† See *Terminus*.

TERMINI, in architecture, denote a kind of statues or columns, adorned a-top with the figure of a man's, woman's, or satyr's head, as a capital; and the lower part ending in a kind of sheath or scabbard.

TERMINUS, in Pagan worship, an ancient deity among the Romans, who presided over the stones or land-marks called *termini*, which were held so sacred that it was accounted sacrilege to move them; and as the criminal became devoted to the gods, it was lawful for any man to kill him. The worship of this deity was instituted by Numa Pompilius, who, to render land-marks, and consequently the property of the people, sacred, erected a temple on the Tarpeian mount to *Terminus*.

TERN, in ornithology. See STERNA.

TERNATE, the most northerly of the Molucca or Clove Islands in the East Indies. It abounds in cocoa-nuts, bananas, citrons, oranges, almonds, and other fruit proper to the torrid zone; but cloves are the most valuable produce. It is in the possession of the Dutch. Malaya is the capital town. E. Long. 125. 10. N. Lat. 1. 15.

TERNI, a town of Italy in the Pope's territories, and in the duchy of Spoleto, with a bishop's see. It is but a small place; though there are very beautiful ruins of antiquity, it having been a very considerable Roman colony. It is situated on the top of a high mountain, and to the west of it are fields which are extremely fertile. E. Long. 12. 50. N. Lat. 42. 4.

TERPANDER, a celebrated Greek poet and musician. The Oxford marbles tell us that he was the son of Derdeneus of Lesbos, and that he flourished in the 381st year of these records; which nearly answers to the 27th olympiad, and 671st year B.C. The marbles inform us likewise, that he taught the *nomos*, or airs, of the lyre and flute, which he performed himself upon this last instrument, in concert with other players on the flute. Several writers tell us that he added three strings to the lyre, which before his time had but four; and in confirmation of this, Euclid and Strabo quote two verses, which they attribute to Terpander himself.

The tetrachord's restraint we now despise,
The seven-string'd lyre a nobler strain supplies.

If the hymn to Mercury, which is ascribed to Homer, and in which the seven-stringed lyre is mentioned, be genuine, it robs Terpander of this glory. The learned, however, have great doubts concerning its authenticity. But if the lyre had been before his time furnished with seven strings in other parts of Greece, it seems as if Terpander was the first who played upon them at Lacedæmon.

Among the many signal services which Terpander is said to have done to music, none was of more importance than the notation that is ascribed to him for ascertaining and preserving melody, which before was traditional, and wholly dependent on memory. The invention, indeed, of musical characters has been attributed by Alypius and Gaudentius, two Greek writers on music, and upon their authority, by Boethius, to Pythagoras, who flourished full two centuries after Terpander. But Plutarch, from Heraclides of Pontus, assures us that Terpander, the inventor of *nomos* for the cithara, in hexameter verse, set them to music, as well as the verses of Homer, in order to sing them at the public games: And Clemens Alexandrianus, in telling us that this musician wrote the laws of *Lycurgus* in verse, and set them to music, makes use of the same expression as Plutarch; which seems clearly to imply a written melody.

After enumerating the airs which Terpander had composed, and to which he had given names, Plutarch continues to speak of his other compositions; among which he describes the poems, or hymns for the cithara, in heroic verse. These were used in after-times by the Rhapsodists, as prologues or introductions to the poems of Homer and other ancient writers. But Terpander rendered his name illustrious, no less by his performance both upon the flute and cithara, than by his compositions. This appears by the marbles already mentioned; by a passage in Athenæus, from the historian Hellanicus, which informs us that he obtained the first prize in the musical contests at the Carnean games; and by the testimony of Plutarch, who says, that "no other proof need be urged of the excellence of Terpander in the art of playing upon the cithara, than what is given by the register of the Pythic games, from which it appears that he gained four prizes successively at those solemnities.

Of the works of this poet only a few fragments are now remaining.

TERRA AUSTRALIS INCOGNITA, a name for a large unknown continent, supposed to lie towards the South Pole, and which for a long time was sought after by navigators. The late voyages of Captain Cook have ascertained this matter as much as it probably ever will be; and though this celebrated navigator does not deny the existence of such a climate, it is by no means probable that ever it will become inhabited, or that any valuable commodity can be produced from it. On this subject Captain Cook expresses himself as follows. "I had now made the circuit of the Southern Ocean in a high latitude, and traversed it in such a manner as to leave not the least room for the possibility of there being a continent, unless near the pole, and out of the reach of navigation. By twice visiting the tropical sea, I had not only settled the situation of some old discoveries, but made there many new ones, and left, I conceive, very little more to be done even in that.

Terra.

that part. Thus I flatter myself, that the intention of the voyage has in every respect been fully answered; the southern hemisphere sufficiently explored; and a final end put to the searching after a southern continent, which has at times ingrossed the attention of some of the maritime powers for near two centuries past, and been a favourite theory amongst the geographers of all ages. That there may be a continent, or large tract of land near the pole, I will not deny: on the contrary, I am of opinion there is; and it is probable that we have seen a part of it. The excessive cold, the many islands and vast floats of ice, all tend to prove that there must be land to the south; and for my persuasion that this southern land must lie or extend farthest to the north, opposite to the Southern Atlantic and Indian Oceans, I have already assigned some reasons; to which I may add the greater degree of cold experienced by us in these seas than in the Southern Pacific Ocean under the same parallels of latitude."

TERRA del Fuego. See *TIERRA del Fuego*.

TERRA Firma, in geography, is sometimes used for a continent, in contradistinction to islands.

TERRA Firma, otherwise called *New Castile*, or *Castilla del Oro*, a country of America, bounded on the north by the North Sea and part of the Atlantic Ocean, by the same sea and Guiana on the east, by the country of the Amazons and Peru on the south, and by the Pacific Ocean and Veragua on the west. It lies between 62 and 83 degrees of west longitude, and between the equator and 12 degrees of north latitude; being upwards of 1200 miles in length from east to west, and 800 in breadth from north to south. It had the name of *Castilla del Oro* from the quantities of gold found in the district of Uraba and other parts; and was first discovered by the celebrated Columbus in his third voyage.

The climate is neither pleasant nor healthy; the inhabitants one part of the year being scorched by the most intense and burning heat, and the other almost drowned with perpetual floods of rain, pouring from the sky with such violence as if a general deluge was to ensue.

In so large a tract of country the soil must necessarily vary. Accordingly, in some parts it is a barren sand, or drowned mangrove land, that will scarce produce any kind of grain; in others it yields Indian corn, balms, gums, and drugs, almost all manner of fruits as well of Old as of New Spain, sugar, tobacco, Brazil wood, and several kinds of dyeing woods; a variety of precious stones, particularly emeralds and sapphires; venison, and other game. The plantations of cacao, or chocolate nuts, in the district of the Caraccas, are esteemed the best in America. The mountains abound with tygers, and, according to some, with lions, and great numbers of other wild beasts. The rivers, seas, and lakes, teem with fish, and also with alligators; and the bowels of the earth were once furnished with the richest treasures, now almost exhausted. The same may be said of the pearl-fisheries on the coast, which are far from being so profitable now as formerly.

TERRA Firma is a very mountainous country. *Terra Firma* Proper, in particular, consists of prodigious high mountains, and deep valleys flooded more than half the year. The mountains in the provinces of Carthage and St Martha, according to Dampier, are

the highest in the world; being seen at sea 200 miles off; from these run a chain of hills of almost equal height, quite through South America, as far as the Straits of Magellan, called the *Cordilleras des Andes*. The province of Venezuela also, and district of the Caraccas, the most northerly parts of South America, are almost a continued chain of hills, separated by small valleys, pointing upon the coast of the North Sea. A chain of barren mountains, almost impassable, runs through the province of Popayan from north to south, some whereof are volcanos; but towards the shores of the Pacific Ocean it is a low country, flooded great part of the year.

The principal rivers of *Terra Firma* are the Darien, Chagtre, Santa Maria, Conception, Rio Grande or Magdalena, Maricao, and Oroonoko.

Terra Firma contains the provinces of *Terra Firma* Proper or Darien, of Carthage, St Martha, Rio de la Hacha, Venezuela, Comana, New Andalusia or Paria, New Granada, and Popayan.

Terra-Firma Proper lies in the form of a crescent, about the spacious bay of Panama, being the isthmus which joins South and North America; and extending in length between the two seas 300 miles, but in breadth, where the isthmus is narrowest, only 60. Here are found gold mines, gold sands, and fine pearls; and though the land is generally rough, there are some fruitful valleys, watered by rivers, brooks, and springs. The chief places are Panama and Porto Bello.

The inhabitants of *Terra Firma* have never been thoroughly subdued, and in all probability never will; as they are a brave and warlike people, have retreats inaccessible to Europeans, and bear an inveterate enmity to the Spaniards.

TERRA Japonica, or *Japan Earth*, improperly so called; being neither an earth nor the produce of Japan; but an inspissated vegetable juice, prepared in the East Indies from the fruit, as is supposed, of the areca palm-tree. It is dry and pulverable, outwardly of a reddish colour, inwardly of a shining dark brown, almost black, with some cast of red. When pure, it dissolves totally in water, and almost totally in rectified spirit; as we usually meet with it, a considerable quantity of sandy matter is left by both these menstrua. This medicine is a mild astringent, and frequently employed as such in alvine fluxes, uterine profluvia, in laxity and debility of the viscera in general, and in coughs proceeding from thin acid disfluxions. Its taste is more agreeable than that of most other substances of this class; chewed for some time, it leaves a sweetness in the mouth. The troches and tincture kept in the shops are very elegant preparations of it.

TERRÆ Filius, *Son of the Earth*, a student of the university of Oxford, formerly appointed in public acts to make satirical and jesting speeches against the members thereof, to tax them with any growing corruptions, &c.

TERRACE, a walk or bank of earth, raised in a garden or court to a due elevation for a prospect. The name is also given to the roofs of houses that are flat, and whereon we may walk.

TERRAQUEOUS, in geography, a name given to our globe, because consisting of land and water.

TERRASSON (Abbe John), a French writer born at Lyons in 1669. He distinguished himself in the

Terra.

Terrestrial
Tertullian.

dispute concerning Homer, between La Motte and Madam Dacier, by writing a *Dissertation contre l'Iliade*; he wrote a political and moral romance called *Sethor*, full of learning and philosophy; and another capital work of his is a French translation of Diodorus Siculus. He died in 1750.

TERRESTRIAL, something partaking of the nature of earth, or belonging to the globe of earth; thus we say, the terrestrial globe, &c.

TERRIER, a small hound, to hunt the fox or badger; so called, because he creeps into the ground, as ferrets do into the coney-burrows after the fox, &c.

TERRITORY, in geography, denotes an extent or compass of land, within the bounds or belonging to the jurisdiction of any state, city, or other subdivision of a country.

TERROR, or **FRIGHT**. The general effects of terror are a great contraction of all the small vessels, and a revulsion of the blood in the large and internal ones; hence the suppression of perspiration, the general oppression, trembling, and anguish, from the heart and lungs being overcharged with blood, &c. After great frights, persons rarely recover their vivacity; and epilepsies that are caused by frights are rarely, if ever, cured. When a person is affected with terror, or sudden or great frights, the principal endeavours should be to restore the circulation to its due order, to promote perspiration, and to allay the agitation or commotion in which the patient is observed to be. The custom of giving cold water in these cases is bad. Place the affrighted person in a quiet situation; a little warm liquor, such as camomile tea, or the like, should be given him to drink; the legs may be put into warm water, and there continue for some time; they should be rubbed, and the camomile tea repeated every six or eight minutes: when the skin becomes warm, and there is a tendency to perspiration, sleep may be promoted by a gentle opiate.

TERTIAN FEVER. See **MEDICINE**, n° 134. 237—248. and p. 4643.

TERTULLIAN, or **QUINTUS SEPTIMUS FLORENS TERTULLIANUS**, a celebrated priest of Carthage, was the son of a centurion in the militia, who served as proconsul of Africa. He was educated in the Pagan religion; but being convinced of its errors, embraced Christianity, and became a zealous defender of the faith. He married, it is thought, after his baptism. Afterwards he took orders, and went to Rome; where, during the persecution under the emperor Severus, he published his *Apology* for the Christians, which is, in its kind, a masterpiece of eloquence and learning; and at the beginning of the third century he embraced the sect of the Montanists. He lived to a very great age, and died under the reign of Antoninus Caracalla about the year 216. Many of his works are still extant, in all of which he discovers a great knowledge of the Holy Scriptures, a lively imagination, a strong, elevated, and impetuous style, great eloquence and strength of reasoning; but is sometimes obscure. His *Apology* and *Prescriptions* are most esteemed. The best editions of his works are those of Rigault; especially that of Venice in 1746, folio. Pamelius and Alix, Mr Thomas, and the Sieur du Fossé, have written his life; and Rigault, M. de l'Aube Epine, Father

Petau, and other learned men, have published notes on his works.

TESSELATED PAVEMENTS, those of rich Mosaic work made of curious square marbles, bricks, or tiles; called *tessele*, from their resembling dice.

TESSON, or **TESTOON**, commonly called *Tesser*, a sort of money which among the French bore the value of 18d.; but being made of brass lightly gilt with silver, in the reign of king Henry VIII. it was reduced to 12d. and afterwards to 6d.

TEST, a large kind of cupel formed of the same materials with the small ones.—Some of the German writers recommend, both for tests and cupels, a sort of friable opake stone, called *white spath*, which appears to be a species of gypsum, or of the stones from which plaster-of-paris is prepared. The spath is directed to be calcined with a gentle fire, in a covered vessel, till the slight crackling, which happens at first, has ceased, and the stone has fallen in part into powder: the whole is then reduced into subtile powder, which is passed through a fine sieve, and moistened with so much of a weak solution of green vitriol as is sufficient for making it hold together. Gellert, however, finds, that if the stone is of the proper kind, which can be known only by trials, calcination is not necessary. Scheffer observes, that these kinds of tests are liable to soften or fall asunder in the fire, and that this inconvenience may be remedied by mixing with the uncalcined stone somewhat less than equal its weight, as eight-ninths of such as has been already used and is penetrated by the scoria of the lead, taking only that part of the old test which appears of a green-grey colour, and rejecting the red crust on the top. Tests or cupels made of the spath are said not to require so much caution in heating and heating them as the common ones: it appears, however, from Scheffer's account, that they are less durable than those made of the ashes of bones, though greatly superior to those of wood-ashes. Vegetable ashes, which stand pretty well the testing of silver, can scarcely bear any great quantity of gold, this metal requiring a considerably stronger fire than the other; but bone-ashes answer so effectually, and are among us so easily procurable, that it is not needful for the refiner to search for any other materials; though those who work off large quantities of lead, in order to gain a little silver or gold contained in it, may possibly, in places remote from populous cities, avail themselves of substances similar to the spath above-mentioned.

The test, for its greater security, is fixed in the mould in which it was formed; which is sometimes a shallow vessel made of crucible earth or cast-iron, more commonly an iron hoop, with three bars arched downwards across the bottom, about two inches deep, and of different widths, from three or four inches to fifteen or more, according to the quantity of metal to be tested at once. The ashes or earthy powder, moistened as for making cupels, are pressed down in the mould so as to completely fill it or rise a little above the sides; with care to make the mass equally solid, and to put in at once, or at least after the bottom has been pressed close, as much of the matter as will be sufficient for the whole; for any additional quantity will not unite thoroughly with the rest, but be apt to

Tesselated
Test.

part

part from it in the fire. The edges are pared smooth, and a portion cut out from the middle with a bent knife, so as to leave a proper cavity, which is smoothed by strewing some dry powder on the surface, and rolling on it a wooden or rather a glass ball.

The process of testing is often performed in the same manner as that of cupellation: but where great quantities of base metal are to be worked off from a little gold, recourse is had to a more expeditious method, that of testing before the bellows.

An oval test is placed in a cavity, made in a hearth of a convenient height, and some moistened sand or ashes pressed round it to keep it steady: the nose of a bellows is directed along its surface, in such a manner, that if ashes are sprinkled in the cavity of the test, the bellows may blow them completely out: some have an iron plate fixed before the bellows, to direct the blast downwards. To keep the surface of the test from being injured in putting in the metal, some cloths or pieces of paper are interposed. The fuel consists of billets of barked oak, laid on the sides of the test, with others laid crosswise on these: the bellows impels the flame on the metal, clears the surface of ashes or sparks of coal, halts the scorification of the lead, and blows off the scoria, as fast as it forms, to one end of the test, where it runs out through a notch made for that purpose. About two-thirds of the scorified lead may thus be collected; the rest being partly absorbed by the test, and partly dissipated by the action of the bellows. Care must be taken not to urge the blast too strongly, lest some portion of the gold should be carried away by the fumes impetuously forced off from the lead, and some minute particles of it entangled and blown off with the scoria.

TEST-AG, a statute 25 Car. II. cap. 2. which requires all officers, both civil and military, to take the oaths and test, viz. the sacrament according to the rites and ceremonies of the church of England; for the neglect whereof, a person executing any office mentioned in that statute, forfeits the sum of 500 l. recoverable by action of debt.

TESTACEOUS, in natural history, an epithet given to a species of fish which are covered with a strong thick shell, as tortoises, oysters, pearl-fish. &c.

TESTAMENT, or LAST-WILL. Testaments both Justinian and Sir Edward Coke agree to be so called, because they are *testatio mentis*: an etymon which seems to favour too much of conceit; it being plainly a substantive derived from the verb *testari*, in like manner as *juramentum*, *incrementum*, and others, from other verbs. The definition of the old Roman lawyers is much better than their etymology; *voluntatis nostræ iusta sententia de eo, quod quis post mortem suam fieri velit*: which may be thus rendered into English, "the legal declaration of a man's intentions, which he wills to be performed after his death." It is called *sententia*, to denote the circumspection and prudence with which it is supposed to be made: it is *voluntatis nostræ sententia*, because its efficacy depends on its declaring the testator's intention, whence in English it is emphatically styled his *will*: it is *iusta sententia*; that is, drawn, attested, and published with all due solemnities and forms of law; it is *de eo, quod*

quis post mortem suam fieri velit, because a testament is Testament, of no force till after the death of the testator.

These testaments are divided into two sorts; written, and verbal or nuncupative: of which the former is committed to writing; the latter depends merely upon oral evidence, being declared by the testator in *extremis* before a sufficient number of witnesses, and afterwards reduced to writing.

But as nuncupative wills and codicils (which were formerly more in use than at present when the art of writing is become more universal), are liable to great impositions, and may occasion many perjuries, the statute of frauds, 29 Car. II. c. 3. enacts, 1. That no written will shall be revoked or altered by a subsequent nuncupative one, except the same be in the lifetime of the testator reduced to writing, and read over to him, and approved; and unless the same be proved to have been so done by the oaths of three witnesses at the least, who, by statute 4 & 5 Anne c. 16. must be such as are admissible upon trials at common law. 2. That no nuncupative will shall in anywise be good, where the estate bequeathed exceeds 30 l. unless proved by three such witnesses, present at the making thereof, (the Roman law requiring seven), and unless they or some of them were specially required to bear witness thereto by the testator himself; and unless it was made in his last sickness, in his own habitation or dwelling-house, or where he had been previously resident ten days at the least, except he be surprised with sickness on a journey, or from home, and dies without returning to his dwelling. 3. That no nuncupative will shall be proved by the witnesses after six months from the making, unless it were put in writing within six days. Nor shall it be proved till fourteen days after the death of the testator, nor till process hath first issued to call in the widow, or next of kin, to contest it if they think proper. Thus hath the legislator provided against any fraud in setting up nuncupative wills, by so numerous a train of requisites, that the thing itself is fallen into disuse; and hardly ever heard of, but in the only instance where favour ought to be shown to it, when the testator is surprised by sudden and violent sickness. The testamentary words must be spoken with an intent to bequeath, not any loose idle discourse in his illness; for he must require the by-standers to bear witness of such his intention: the will must be made at home, or among his family or friends, unless by unavoidable accident, to prevent impositions from strangers: it must be in his last sickness; for, if he recovers, he may alter his dispositions, and has time to make a written will: it must not be proved at too long a distance from the testator's death, lest the words should escape the memory of the witnesses; nor yet too hastily and without notice, lest the family of the testator should be put to inconvenience, or surprised.

As to written wills, they need not any witness of their publication. We speak not here of devises of lands, which are entirely another thing, a conveyance by statute, unknown to the feudal or common law, and not under the same jurisdiction as personal testaments. But a testament of chattels, written in the testator's own hand, though it has neither his name nor seal to it, nor witnesses present at its publication,

Testament. tion, is good; provided sufficient proof can be had that it is his hand-writing. And though written in another man's hand, and never signed by the testator, yet if proved to be according to his instructions and approved by him, it hath been held a good testament of the personal estate. Yet it is the safer and more prudent way, and leaves less in the breast of the ecclesiastical judge, if it be signed or sealed by the testator, and published in the presence of witnesses: which last was always required in the time of Bracton; or rather he in this respect has implicitly copied the rule of the civil law.

No testament is of any effect till after the death of the testator; *Nam omne testamentum mortis consummatum est, et voluntas testatoris est ambulatoria usque ad mortem.* And therefore, if there be many testaments, the last overthrows all the former; but the republication of a former will revoke one of a later date, and establishes the first again.

Regularly, every person hath full power and liberty to make a will, that is not under some special prohibition by law or custom: which prohibitions are principally upon three accounts; for want of sufficient discretion; for want of sufficient liberty and free-will; and on account of their criminal conduct.

1. In the first species are to be reckoned infants, under the age of 14 if males, and 12 if females; which is the rule of the civil law. For though some of our common lawyers have held that an infant of any age (even four years old) might make a testament, and others have denied that under 18 he is capable; yet as the ecclesiastical court is the judge of every testator's capacity, this case must be governed by the rules of the ecclesiastical law. So that no objection can be admitted to the will of an infant of 14, merely for want of age: but if the testator was not of sufficient discretion, whether at the age of 14 or 24, that will overthrow his testament. Madmen, or otherwise *non compos*, idiots or natural fools, persons grown childish by reason of old age or distemper, such as have their senses befogged with drunkenness,—all these are incapable, by reason of mental disability, to make any will so long as such disability lasts. To this class also may be referred such persons as are born deaf, blind, and dumb; who, as they have always wanted the common inlets of understanding, are incapable of having *animum testandi*, and their testaments are therefore void.

2. Such persons as are intestable for want of liberty or freedom of will, are by the civil law of various kinds; as prisoners, captives, and the like. But the law of England does not make such persons absolutely intestable; but only leaves it to the discretion of the court to judge upon the consideration of their particular circumstances of duress, whether or no such persons could be supposed to have *liberum animum testandi*. And, with regard to feme-coverts, our laws differ still more materially from the civil. Among the Romans there was no distinction; a married woman was as capable of bequeathing as a feme-sole. But with us a married woman is not only utterly incapable of devising lands, being excepted out of the statute of wills, 34 & 35 Hen. VIII. c. 5. but also she is incapable of making a testament of chattels, without the licence of her husband. For all her

personal chattels are absolutely his own; and he may dispose of her chattels real, or shall have them to himself if he survives her: it would be therefore extremely inconsistent to give her a power of defeating that provision of the law, by bequeathing those chattels to another. The queen-consort is an exception to this general rule, for she may dispose of her chattels by will, without the consent of her lord; and any feme-covert may make her will of goods which are in her possession in *auter droit*, as executrix or administratrix; for these can never be the property of the husband: and if she has any pin-money or separate maintenance, it is said she may dispose of her savings thereof by testament, without the controul of her husband. But if a feme-sole makes her will, and afterwards marries, such subsequent marriage is esteemed a revocation in law, and entirely vacates the will.

3. Persons incapable of making testaments, on account of their criminal conduct, are in the first place all traitors and felons, from the time of conviction; for then their goods and chattels are no longer at their own disposal, but forfeited to the king. Neither can a *felo de se* make a will of goods and chattels, for they are forfeited by the act and manner of his death; but he may make a devise of his lands, for they are not subjected to any forfeiture. Outlaws also, though it be but for debt, are incapable of making a will so long as the outlawry subsists, for their goods and chattels are forfeited during that time. As for persons guilty of other crimes, short of felony, who are by the civil law precluded from making testaments, (as usurers, libellers, and others of a worse stamp), at the common law their testaments may be good. And in general the rule is, and has been so at least ever since Glanvil's time, *quod libera sit cujusunque ultima voluntas*.

Testaments may be avoided three ways: 1. If made by a person labouring under any of the incapacities before-mentioned; 2. By making another testament of a later date; and, 3. By cancelling or revoking it. For tho' I make a last will and testament irrevocable in the strongest words, yet I am at liberty to revoke it: because my own act or words cannot alter the disposition of law, so as to make that irrevocable which is in its own nature revocable. For this, saith lord Bacon, would be for a man to deprive himself of that which of all other things is most incident to human condition; and that is, alteration or repentance. It hath also been held, that, without an express revocation, if a man, who hath made his will, afterwards marries and hath a child, this is a presumptive or implied revocation of his former will which he made in his state of celibacy. The Romans were also wont to set aside testaments as being *inefficacia*, deficient in natural duty, if they disinherited or totally passed by (without assigning a true and sufficient reason) any of the children of the testator. But if the child had any legacy, though ever so small, it was a proof that the testator had not lost his memory or his reason, which otherwise the law presumed; but was then supposed to have acted thus for some substantial cause: and in such case *no querela inofficiosi testamenti* was allowed. Hence probably has arisen that groundless vulgar error of the necessity of leaving the heir a shilling, or some other express legacy, in order to disinherit him effectually: whereas, the

Testament the law of England makes no such wild supposition of forgetfulness or infancy; and therefore, though the heir or next of kin be totally omitted, it admits no *inofficiis* to set aside such a testament.

TESTAMENT, in Scots law. See LAW, N° clxxxi. 2, &c.

TESTAMENT, (Old and New). See BIBLE.

TESTATOR, the person who makes his will and testament.

TESTER. See TESSON.

TESTES, in anatomy, the testicles. See the next article.

TESTICLE (*testis*), a double part in animals of the male kind, serving for the office of generation.—See ANAT. n° 371. They are called *testicles*, by diminution of *testis*, “witnesses;” as giving testimony of virility. The Greeks call them *didymi*, or *twins*.

In man and most animals, the testicles are exterior; in some, as fowls, interior. Some men have only one, ordinarily they have two; some have naturally had three; nay, anatomists assure us they have known four.

TESTIMONY. See LOGIC, n° 29. and METAPHYSICS, n° 253.—260.

TESTIMONY, in law. See EVIDENCE.

TESTUDO, the TORTOISE, in zoology, the name of a genus belonging to the order of amphibia reptilia. It has four legs and a tail, and the body is covered with a strong shell. There are 15 species, principally distinguished by peculiarities in their feet. The midas, or common turtle, is found on the Ascension Isle, and on many other southern islands. The shell is so strong, that several men may stand on it without doing it any injury. It digs round holes in the sand, in which it lays several membranaceous eggs. It grows to a very large size; some having been found weighing 480 lb. These creatures are said to continue several weeks in the act of copulation.

The Americans find no good account in catching turtle, that they have made themselves very expert at it: they watch them from their nests on shore, in moon-light nights; and, before they reach the sea, turn them on their backs, and leave them till morning; when they are sure to find them, since they are utterly unable to recover their former posture: at other times they hunt them in boats, with a peculiar kind of spear, striking them with it through the shell; and as there is a cord fastened to the spear, they are taken much in the same manner as the whales.

TESTUDO, in antiquity, was particularly used among the poets, &c. for the ancient lyre; by reason it was originally made by its inventor Mercury, of the black or hollow of the *testudo aquatica*, or sea-tortoise, which he accidentally found on the banks of the river Nile. See LYRE.

TESTUDO, in the military art of the ancients, was a kind of cover or screen which the soldiers, *e. gr.* a whole company, made themselves of their bucklers, by holding them up over their heads, and standing close to each other. This expedient served to shelter them from darts, stones, &c. thrown upon them, especially those thrown from above, when they went to the assault.

TESTUDO, was also a kind of large wooden tower which moved on several wheels, and was covered with bullock-hides, serving to shelter the soldiers when

they approached the walls to mine them, or to batter them with rams. It was called *testudo*, from the strength of its roof, which covered the workmen as the shell does the tortoise.

TETANUS, a dreadful spasmodic disorder, in which the whole body becomes rigid and inflexible. It most commonly proves mortal. See MEDICINE, n° 387. 389.

TETHYS, a genus of insects belonging to the order of vermes mollusca. The body is oblong, fleshy, and without feet; the mouth consists of a cylindrical proboscis under the duplicature of a lip; and there are two foramina at the left side of the neck. The species are two, both inhabitants of the ocean.

TETRADYNAMIA, (*tetraxis* “four,” and *dynamis* “power”), four powers; the name of the 15th class in Linnaeus’s Sexual System, consisting of plants with hermaphrodite flowers, having six stamina, four of which are long, and two short; it corresponds to the *filipsose* of Ray, and *cruciformes* of Tournefort. See BOTANY, p. 1296.

TETRAGYNIA, (*tetraxis*, “four,” and *gyn* “a woman”); the name of an order, or secondary division in the 4th, 5th, 6th, 8th, and 13th classes in the Sexual System; consisting of plants which, to the classic character, whatever it is, add the circumstance of having four styles or female organs. Herb-paris and grafs of *Parnassius* furnish examples.

TETRANDRIA, (*tetraxis* “four,” and *and* “a man or husband”); the name of the fourth class in Linnaeus’s Sexual System, consisting of plants with hermaphrodite flowers, which have four stamina or male organs that are of equal length. In this last circumstance consists the main difference, according to Linnaeus, between the plants of the class in question and those of the 14th class, didynamia, in which the four stamina are of unequal length, two of them being long, and two short.—The orders in this numerous class are three, founded upon the number of styles or female organs. Scabious, teal, barren-wort, the starry plants of Ray, and the greater number of genera in this class, have one style; dodder, and hypericum have two; holly, and a few others, have four.

TETRAO, in ornithology, a genus of birds, belonging to the order of gallinæ, distinguished by having the part of the forehead near the eyes naked and papillose. There are many species, distinguished principally by their colour, their having rump, or naked feet, &c. The following are found in Britain, viz.

1. The urogallus, or wood-cock, inhabits wooded and mountainous countries; in particular, forests of pines, birch-trees and junipers; feeding on the tops of the former and berries of the latter; the first insects often the flesh with such a taste as to render it scarcely eatable. In the spring it calls the females to its haunts with a loud and shrill voice; and is at that time so very inattentive to its safety, as to be very easily shot. It stands perched on a tree, and descends to the females on their first appearance. They lay from 8 to 16 eggs; eight at the first, and more as they advance in age.

These birds are common to Scandinavia, Germany, France, and several parts of the Alps.—It is found in no other part of Great Britain than the Highlands

lands of Scotland, north of Inverness; and is very rare even in those parts. It is there known by the name of *capercalze*, *auer-calze*, and in the old law books *caperkally*; the last signifying the horse of the woods: this species being, in comparison of others of the genus, pre-eminently large.

The length of the male is two feet eight inches; its weight sometimes 14 pounds. The female is much less, the length being only 26 inches. The sexes differ also greatly in colours. The bill of the male is of a pale yellow; the head, neck, and back, are elegantly marked, slender lines of grey and black running transversely. The upper part of the breast is of a rich glossy green; the rest of the breast and the belly black, mixed with some white feathers; the sides are marked like the neck; the coverts of the wings crossed with undulated lines of black and reddish brown; the exterior webs of the greater quill-feathers are black: the tail consists of 18 feathers, the middle of which is the longest; these are black, marked on each side with a few white spots. The legs are very strong, and covered with brown feathers; the edges of the toes are pectinated.—Of the female, the bill is dusky; the throat red; the head, neck, and back, are marked with transverse bars of red and black: the breast has some white spots on it, and the lower part is of a plain orange colour: the belly is barred with pale orange and black; the tips of the feathers are white. The tail is of a deep rust-colour barred with black, tipped with white, and consists of 16 feathers.

2. The tetrix, or black-cock, like the former species, is fond of wooded and mountainous situations; feeding on bilberries and other mountain fruits, and in the winter on the tops of the heath. In the summer they frequently descend from the hills to feed on corn. They never pair: but in the spring the male gets upon some eminence, crows and claps his wings; on which signal all the females within hearing resort to him. The hen lays seldom more than six or seven eggs. When the female is obliged, during the time of incubation, to leave her eggs in quest of food, she covers them up so artfully, with moss or dry leaves, that it is very difficult to discover them. On this occasion she is extremely tame and tranquil, however wild and timorous in ordinary. She often keeps to her nest, though strangers attempt to drag her away. As soon as the young ones are hatched, they are seen running with extreme agility after the mother, though sometimes they are not entirely disengaged from the shell. The hen leads them forward for the first time into the woods, to show them ants eggs and the wild mountain-berries, which, while young, are their only food. As they grow older their appetites grow stronger, and they then feed upon the tops of heather and the cones of the pine-tree. In this manner they soon come to perfection: they are an hardy bird, their food lies every where before them, and it would seem that they should increase in great abundance. But this is not the case; their numbers are thinned by rapacious birds and beasts of every kind, and still more by their own salacious contests.—As soon as the clutching is over, which the female performs in the manner of an hen, the whole brood follows the mother for about a month or two; at the end of which the young males entirely forsake her, and keep in great harmony together till the be-

ginning of spring. At this season they begin for the first time to feel the genial access; and then adieu to all their former friendships! They begin to consider each other as rivals; and the rage of concupiscence quite extinguishes the spirit of society. They fight each other like game-cocks; and at that time are so inattentive to their own safety, that it often happens that two or three of them are killed at a shot. It is probable, that in these contests the bird which comes off victorious takes possession of the female scragio, as it is certain they have no faithful attachments.

An old black cock is in length 22 inches, and weighs near four pounds. The bill is dusky; and the plumage of the whole body black, glossed over the neck and rump with a shining blue. The coverts of the wings are of a dusky brown; the inner coverts white; the thighs and legs are covered with dark brown feathers; the toes resemble those of the former species. The tail consists of 16 black feathers, and is much forked; the exterior feathers bend greatly upwards, and their ends seem as if cut off.—The female weighs only two pounds; and its length is one foot six inches. The head and neck are marked with alternate bars of dull red and black; the breast with dusky black and white; but the last predominates. The back, coverts of the wings, and tail, are of the same colours as the neck, but the red is deeper. The tail is slightly forked; it consists of 18 feathers variegated with red and black. The feathers under the tail are white, marked with a few bars of black and orange. This bird hatches its young late in the summer. It lays from six to eight eggs, of a dull yellowish white colour, marked with numbers of very small ferruginous specks; and towards the smaller end with some blotches of the same hue.

3. The red game, or moor-fowl, is peculiar to the British islands. The male weighs about 19 ounces; and is in length 15½ inches. The bill is black; the irides hazel-coloured. The throat is red. The plumage on the head and neck is of a light tawny red; each feather is marked with several transverse bars of black. The back and scapular feathers are of a deeper red, and on the middle of each feather is a large black spot; the breast and belly are of a dull purplish brown, crossed with numerous narrow dusky lines; the quill-feathers are dusky; the tail consists of 16 feathers of an equal length, all of them (except the four middlemost) are black, and the middle feathers are barred with red: the thighs are of a pale red, barred obscurely with black; the legs and feet clothed to the very claws with thick soft white feathers. The claws are whitish, very broad and strong. The female weighs only 15 ounces. The colours in general are duller than those of the male: the breast and belly are spotted with white; and the tips of some of the coverts of the wings are of the same colour.—These birds pair in the spring, and lay from six to ten eggs. The young brood follow the hen the whole summer; in the winter they join in flocks of 40 or 50, and become remarkably shy and wild; they always keep on the tops of the hills, are scarce ever found on the sides, and never descend into the valleys. Their food is the mountain-berries and tops of the heath.

4. The lagopus, or ptarmigan, is 15 inches in length, and weighs 19 ounces. Its plumage is of a pale brown or ash colour, elegantly crossed or mottled with small dusky spots, and minute bars; the head and neck with
broad

broad bars of black, rust-colour, and white: the belly and wings are white, but the shafts of the greater quill-feathers black. In the male, the grey colour predominates, except on the head and neck, where there is a great mixture of red, with bars of white. The females and young birds have a great deal of rust-colour in them. The tail consists of 16 feathers; the two middle of which are ash-coloured, mottled with black, and tipped with white; the two next black, slightly marked with white at their ends, the rest wholly black: the feathers incumbent on the tail are white, and almost entirely cover it.

Ptarmigans are found in these kingdoms only on the summits of the highest hills of the Highlands of Scotland and of the Hebrides; and a few still inhabit the lofty hills near Keswick in Cumberland. They live amidst the rocks, perching on the grey stones, the general colour of the frata to those exalted situations. They are very filly birds; so tame as to bear driving like poultry; and, if provoked to rise, take very short flights, making a small circuit like pigeons. Like the grouse, they keep in small packs; but never, like those birds, take shelter in the heath, but beneath loose stones. To the taste they scarce differ from a grouse.

These birds are called by Pliny, *laggi*, their feet being clothed with feathers to the claws, as the hare's are with fur: the nails are long, broad, and hollow. The first circumstance guards them from the rigour of the winter; the latter enables them to form a lodge under the snow, where they lie in heaps to protect them from the cold. The feet of the grouse are clothed in the same manner; but those of the two first species here described, which perch upon trees, are naked, the legs only being feathered, not being in want of such a protection.—In Scotland, they inhabit from the hill of Ben Lomond to the naked mountain of Scaraben in Caithness, the isle of Arran, many of the Hebrides and the Orkneys.

5. The perdriz, or partridge, is so well known, as to render any technical description unnecessary.

“These birds (says Willoughby) hold the principal place in the feasts and entertainments of princes; without which their feasts are esteemed ignoble, vulgar, and of no account. The Frenchmen do so highly value, and are so fond of the partridge, that if they be wanting, they utterly slight and despise the best spread tables; as if there could be no feast without them.” But however this might be in the times of our historian, the partridge is now too common in France to be considered as a delicacy; and this, as well as every other simple dish, is exploded for luxuries of a more compound invention. In England, where the partridge is much scarcer, and a great deal dearer, it is still a favourite delicacy at the tables of the rich; and the desire of keeping it to themselves has induced them to make laws for its preservation, no way harmonising with the general spirit of English legislation.

The partridge seems to be a bird well known all over the world, as it is found in every country and in every climate; as well in the frozen regions about the pole, as the torrid tracks under the equator. It even seems to adapt itself to the nature of the climate where it resides. In Greenland, the partridge, which is brown in summer, as soon as the icy winter sets in, begins to take a covering suited to the season: it is then clothed

with a warm down beneath; and its outward plumage assumes the colour of the snow amongst which it seeks its food. Thus it is doubly fitted for the place, by the warmth and the colour of its plumage; the one to defend it from the cold, the other to prevent its being noticed by the enemy. Those of Barankonda, on the other hand, are longer legged, much swifter of foot, and choose the highest rocks and precipices to reside in.—They all, however, agree in one character, of being immoderately addicted to venery; and, as some writers affirm, often to an unnatural degree. It is certain, the male will pursue the hen even to her nest; and will break her eggs rather than not indulge his inclinations. Though the young ones have kept together in flocks during the winter, when they begin to pair in spring their society disperses; and combat, very terrible with respect to each other, ensue. Their manners in other circumstances, resemble all those of poultry in general; but their cunning and insinect seem superior to those of the larger kinds. Perhaps, as they live in the very neighbourhood of their enemies, they have more frequent occasion to put their little arts in practice, and learn by habit the means of evasion or safety. Whenever therefore a dog or other formidable animal approaches their nest, the female uses every means to draw him away. She keeps just before him, pretends to be incapable of flying, just hops up, and then falls down before him, but never goes off so far as to discourage her pursuer. At length, when she has drawn him entirely away from her secret treasure, she at once takes wing, and fairly leaves him to gaze after her in despair. After the danger is over, and the dog withdrawn, she then calls her young, who assemble at once at her cry, and follow where she leads them. There are generally from 10 to 15 in a covey; and, if unmolested, they live from 15, to 17 years. There are several methods of taking them, as is well known; that by which they are taken in a net with a setting dog, is the most pleasant, as well as the most secure. The dog, as every body knows, is trained to this exercise by a long course of education: by blows and caresses he is taught to lie down at the word of command; a partridge is shown him, and he is then ordered to lie down; he is brought into the field, and when the sportsman perceives where the covey lies, he orders his dog to crouch: at length the dog, from habit, crouches wherever he approaches a covey; and this is the signal which the sportsman receives for unfolding and covering the birds with his net. A covey thus caught, is sometimes fed in a place proper for their reception; but they can never be thoroughly tamed like the rest of our domestic poultry.

6. The coturnix, or quail, is not above half the size of the partridge. The feathers of the head are black, edged with rusty brown; the breast is of a pale yellowish red, spotted with black; the feathers on the back are marked with lines of pale yellow, and the legs are of a pale hue. Except in the colours thus described, and the size, it every way resembles a partridge in shape, and, except that it is a bird of passage, all others of the poultry kind in its habits and nature.

The quail is by all known to be a bird of passage; and yet, if we consider its heavy manner of flying, and its scantiness of plumage with respect to its corpulence, we shall be surprised how a bird so apparently ill qua-

Tetrao,
Tetraodon.

lified for migration, should take such extensive journeys. This, however, is asserted: "When we sailed from Rhodes to Alexandria (says Bellonius) about autumn, many quails, flying from the north to south, were taken in our ship; and sailing at spring-time the contrary way, from the south to the north, I observed them on their return, when many of them were taken in the same manner." The same account is given by many others; who aver, that they choose a north wind for these adventures; the south wind being very unfavourable, as it retards their flight by moistening their plumage. They then fly two by two; continuing, when their way lies over land, to go faster by night than by day; and to fly very high, to avoid being surprised or set upon by birds of prey. However, it still remains a doubt whether quails take such long journeys as Bellonius has made them perform. It is now asserted by some, that the quail only migrates from one province of a country to another. For instance, in England they fly from the inland counties to those bordering on the sea, and continue there all the winter. If frost or snow drive them out of the stubble-fields or marshes, they then retreat to the sea-side, shelter themselves among the weeds, and live upon what is thrown up from the sea upon shore. Particularly in Essex, the time of their appearance upon the coasts of that country exactly coincides with their disappearance from the more internal parts of the kingdom; so that what has been said of their long flights, is probably not so well founded as is generally supposed.—These birds are much less prolific than the partridge; seldom laying more than six or seven whitish eggs, marked with ragged rust-coloured spots. But their ardour in courtship yields scarce to any other bird, as they are fierce and cruel at that season to each other, fighting most desperately, and (a punishment they richly deserve) being at that time very easily taken. Quail-fighting was favourite amusement among the Athenians. They abstained from the flesh of this bird, deeming it unwholesome, as supposing that it fed upon the white hellebore: but they reared great numbers of them for the pleasure of seeing them fight; and staked sums of money, as we do with regard to cocks, upon the success of the combat. Fashion, however, has at present changed with regard to this bird; we take no pleasure in its courage, but its flesh is considered as a very great delicacy.—Quails are easily caught by a call: the fowler early in the morning having spread his net, hides himself under it among the corn; he then imitates the voice of the female with his quail-pipe, which the cock hearing, approaches with the utmost assiduity; when he has got under the net, the fowler then discovers himself, and terrifies the quail, who attempting to get away, entangles himself the more in the net, and is taken.

TETRAODON, a genus of fishes, belonging to the order of amphibia nantes. The jaws are bony, stretched out, and cloven at the point: there is a linear aperture; no ventral fins. There are seven species; of which the most remarkable is the lineatus, called by Mr. Harselquist *Jabaka*, which is the Egyptian and Arabic name. It has of late been found in the Nile about Cairo, but was never known in former times. It is said to grow to a prodigious size. When just caught, it pricks the skin if it is taken in the bare hands, and

produces small pustules in the same manner as nettles. The flesh is poisonous. Mr. Forster confirms the account of the poisonous nature of a species of tetraodon, in his account of *New CALEDONIA*.

TETRARCH, a prince who holds and governs a fourth part of a kingdom. Such originally was the import of the title *tetrarch*; but it was afterwards applied to any petty king or sovereign.

TETRASTYLE, in the ancient architecture, a building, and particularly a temple, with four columns in its front.

TETUAN, an ancient and pleasant town of Africa, in the kingdom of Fez, and in the province of Habata. It is pretty well built, and the inhabitants are about 15,000 in number, who call themselves *Andalusians*, and almost all speak Spanish; but they are great pirates. Some say there are 30,000 Moorish inhabitants, and 5000 Jews. W. Long. 5. 18. N. Lat. 35. 25.

TEUCRIUM, **TREE GERMANDER**, a genus of the gymnospermia order, belonging to the didynamia class of plants.

There are many species; of which the most remarkable are, 1. The *flavum*, yellow shrubby *teucrium*, commonly called *tree germander*; rising with erect shrubby stalks and branches, only a foot and a half or two feet high; having small heart-shaped, obtusely serrated, foot-stalked leaves, hoary underneath, with the floral leaves concave and entire; and numerous flowers by threes, in whorls, along the upper part of the branches, of different colours in the varieties. This shrub is durable in root, stem, and branches, foliated most part of the year, and produces flowers ornamentally in July, succeeded by ripe seed in autumn. It is an exotic from Spain and Italy, long since introduced into our gardens; formerly kept as a green-house plant, but now is sufficiently naturalized to this climate to succeed in the open air all the year. 2. The *scordium*, or common water-germander, hath creeping perennial roots, sending up many square, procumbent, or trailing stalks, branching diffusely; oblong, indented, serrated, close-fitting, opposite leaves; and small redish flowers, generally two together, from the sides of the stalks and branches, in July and August. This is a medicinal herb, and smells strongly of garlic. It grows naturally in marshy places, in the isle of Ely and other parts of England, and most parts of Europe; and sometimes admitted in gardens, in moist places, for variety, and as a medical plant. 3. The *chamaedrys*, or smaller creeping germander, hath fibrous, very creeping, spreading roots; many four-cornered, very branchy, trailing stalks, near a foot long; oval, cuneiform, cut, crenated leaves on short foot-stalks; and redish flowers, growing almost in a verticillus, or whorls, round the stalk, three on each peduncle; appearing in June and July. Is a native of Germany, France, &c. 4. The *polium*, or common yellow mountain-poly, hath a fibrated perennial root; herbaceous, trailing, branchy stalks, prostrate on the ground; oblong, obtuse, crenated, downy, sessile leaves; and the branches terminated by roundish heads of yellow and other coloured flowers in the varieties; appearing in June and July. There are many varieties of this species, distinguished by some little variation in their growth,

Tetrarch
Teucrium

Teutones,
Teutonic.

growth, having all roundish heads of flowers; mostly, however, either white or yellow. It grows naturally in Spain and Portugal, &c. 5. The montanum, mountain-poly, with lavender leaves, hath a fibrous, tough, ligneous root; somewhat ligneous, weak, procumbent stalks; spear-shaped entire leaves, hoary underneath; and small white flowers in a corymbus at the termination of the branches, in June and July. They are all perennial plants, durable in root; and some of the ligneous kinds are also abiding in stalk, more particularly some of the polyiums. The leaves and seed of the chamædryas have been recommended as diuretic, sudorific, and emmenagogue; but are now very little used.

TEUTONES, or TEUTONI, (anc. geog.) a people always by historians joined with the Cimbri; both seated, according to Mela, beyond the Elbe, on the Sinus Codanus, or Baltic; and there, it is supposed, lay the country of the Teutones, now *Ditmarsh*; diversity of dialects producing the different terms *Teut*, *Tut*, *Dit*, *Tid*, and *Thod*, which in the ancient German language signified *people*. Of these Teutones, Virgil is to be understood in the epithet *Teutonicus*, an appellation which more lately came to be applied to the Germans in general, and later still the appellation *Alemanni*.

The Teutones, in conjunction with the Cimbri and Ambrones, made war on the Romans, and marched towards Italy in the year 101 B. C. We are told, that the Teutones alone were so numerous, that they were six whole days without intermission in passing by the Roman camp. In Transalpine Gaul they engaged the Roman consul Marius; but were defeated with incredible slaughter; 100,000 of them, according to the lowest calculations, being killed on the spot. According to others, the number of those killed and taken prisoners amounted to 200,000. The inhabitants of the neighbouring country made fences for vineyards of their bones. Their king Teutobochus, said to be a monstrous giant, was taken prisoner and carried to Rome. See the article *GIANT*.

TEUTONIC, something belonging to the Teutones. The Teutonic is supposed to have been the language of the ancient Germans, and hence is reckoned amongst the mother-tongues. The German or Dutch is still called the *Teutonic*.

TEUTONIC Order, an order of military knights, established towards the close of the twelfth century, on the following occasion.—When the emperor Barbarossa engaged in a crusade for the recovery of the Holy Land out of the hands of Saladin, he was followed by great numbers of German volunteers, who from various motives enlisted under his banners. After the death of Barbarossa, the Germans, who had signalized themselves before Acre or Ptolemais, resolved to choose another leader; and at last fixed their choice upon Frederic duke of Suabia, second son to the emperor and Henry duke of Brabant. Under these generals they behaved with so much bravery, that Henry king of Jerusalem, the patriarch, and several other princes, determined to reward their valour by instituting an order of knighthood in their favour. This was accordingly done; and our new knights had at first the title of the *knights of St George*; afterwards it was thought proper to put them under the tutelage of the

Virgin Mary, to whom there was already a hospital dedicated on Mount Zion, for the relief of German pilgrims. From this time they were called *Equites Mariani*, or knights of St Mary. Laws, regulations, and statutes, were drawn up for them by the Christian kings in Syria and the patriarch; and among other obligations it was required, that every person admitted to the privileges of the order should be of noble parentage; that the order should defend the Christian religion, and the Holy Land; that they should exercise hospitality towards the Christians in general, but particularly those of their own country; and that they should with all their power endeavour to propagate and extend the Christian faith and the religion of JESUS. In the year 1190, having become rich by donations from the superstitious, they elected their first grandmaster, Henry Walpot, a German, who had distinguished himself by his zeal and valour; and their choice was confirmed by the emperor. The following year, pope Celestine III. confirmed their privileges already granted, giving them the title of the *Teutonic knights of the hospital of St Mary the Virgin*. By the conditions of this bull, they vowed perpetual continence, obedience, and poverty; obligations which it may well be imagined were not very strictly kept.

TEWKSBURY, a town in Gloucestershire, formerly noted for its monastery. It is now a large handsome corporation, containing about 500 houses, with a magnificent church. It is seated at the confluence of the rivers Severn and Avon, has a cotton manufactory, and sends two members to parliament. W. Long. 2. 15. N. Lat. 52. 0.

TEXEL, a town of the United Provinces, in N. Holland, seated at the mouth of the Zuyder-Zee, with a good harbour, and a strong fort. It is seated in an island, which is separated from the continent of Holland by a narrow channel, through which most of the ships pass that are bound to Amsterdam. E. Long. 4. 25. N. Lat. 53. 12.

TEXT, a relative term, contradistinguished to gloss or commentary, and signifying an original discourse exclusive of any note or interpretation. This word is particularly used for a certain passage of scripture, chosen by a preacher to be the subject of his sermon.

TEXTURE, properly denotes the arrangement and cohesion of several slender bodies or threads interwoven or entangled among each other, as in the webs of spiders, or in the cloths, ruffs, &c.

Texture is also used in speaking of any union or constituent particles of a concrete body, whether by weaving, hooking, knitting, tying, chaining, indenting, intruding, compressing, attracting, or any other way. In which sense we say, a close compact texture, a lax porous texture, a regular or irregular texture, &c.

THABOR, or TABOR, (anc. geog.) a mountain of Galilee, situated in a plain, and equally terminated or defined on every side; lying in the middle between the Campus Magnus or Great Plain, and Scythopolis. This mountain was the boundary of Issachar to the north, on the borders of Zabulon; and, according to Lightfoot, was distant about 10 miles to the north-west of Capernaum; which agrees with the relations of travellers. The most beautiful mountain in the world, both

Teutonic
Thabor.

in itself, and in the prospect it affords. Seen on the east and west sides, it exactly resembles a sugar-loaf; on the north and south sides, it appears of an oval round, with a deep valley running about it, so as to lie detached from, though near to, the other mountains, which it overtops. To the north-east, the east, and south-east, it has the plain of Galilee lying before it, and to the south and south-west the incomparably beautiful plain of Esdrelon; quite round, it rises equally high and steep, and appears green on every side, (Korte). A top, it has an oval plain about three miles in compass. Over the plain of Esdrelon there is a view of the mountains of Gilead; to the south, and to the south-west, that of Mount Carmel; to the west, a prospect of the mountains of Nazareth, and over them of the Mediterranean; and to the north that of the beginning of Lebanon, and then that of Bashan, (*I. bid.*) At this mountain Barak collected the army he raised against Sisera, and in the plain below fought with him. Whether this was the high mountain on which our Saviour's transfiguration happened, mentioned by the evangelists, though affirmed by the generality, is however questioned by some. Ancient tradition is for it: whereas Lightfoot will have it to be a mountain near Cæsarea Philippi; probably that very high one which, according to Josephus, hangs over the springs of the Jordan, and at the foot of which stood Cæsarea.

THALES, a celebrated Greek philosopher, and the first of the seven wise men of Greece, was born at Miletum, about 640 B. C. In order to improve himself in the knowledge of the sciences, he travelled into Egypt, where he discoursed with the priests and other learned men. Some say that he married: but others observe, that he eluded the solicitations of his mother on this head, by telling her, when he was young, that it was too soon; and afterwards, that it was too late. Thales acquired great reputation by his wisdom and learning: he was the first among the Greeks who foretold eclipses of the sun, and made extraordinary discoveries in astronomy. Thales was the author of the Ionian sect of philosophers, who were thus called from his being born at Miletum, a city of Ionia. He maintained, that water was the principle of which all the bodies in the universe are composed; that the world was the work of God; and that God sees the most secret thoughts in the heart of man. He said, That "the most difficult thing in the world is to know ourselves; the most easy, to advise others; and the most sweet, to accomplish our desires. That, in order to live well, we ought to abstain from what we find fault with in others. That bodily felicity consists in health; and that of the mind in knowledge. That the most ancient of beings is God, because he is uncreated: that nothing is more beautiful than the world, because it is the work of God; nothing more extensive than space quicker than spirit, stronger than necessity, wiser than time." It was also one of his sentences, That "we ought never to say that to any one that may be turned to our prejudice; and that we should live with our friends as with persons that may become our enemies." He thanked God for three things; that he was born of the human, not of the brute species; a man, and not a woman; a Greek, and not a barbarian. None of the ancient philosophers ever applied

themselves more earnestly to the study of astronomy than Thales. Diogenes Laertius reports, that leaving his lodging with an old woman to contemplate the stars, he fell into a ditch; on which the good woman cried, "How canst thou know what is doing in the heavens, when thou canst not perceive what is at thy feet?" He went to see Croesus, who was marching with a powerful army into Cappadocia, and enabled him to pass the river Halys without making a bridge. Thales died soon after, at above 90 years of age. He composed several treatises in verse, on meteors, the equinoxes, &c. but they are all lost.

THALETAS, an ancient Greek poet and musician, was, according to Plutarch, cotemporary with Lycurgus the Spartan legislator, and lived about 300 years after the Trojan war. Plutarch also informs us, that though Thaletas was only styled a lyric poet and musician, he was likewise a great philosopher and politician; inasmuch, that Lycurgus brought him from Crete when he returned from his travels to Sparta, in order to have assistance from him in establishing his new form of government. His odes, continues Plutarch, were so many exhortations to obedience and concord, which he enforced by the sweetness of his voice and melody. Plato likewise describes his captivating manner of singing; and Plutarch, in his Dialogue on Music, ascribes to Thaletas many musical compositions and inventions: such as *psalmi*, and new measures in verse, as well as *rhythmi* in music, which he had acquired from the flute-playing of Olympus, whom he at first had imitated. Porphyry, in his life of Pythagoras, says, that this philosopher used to amuse himself with singing the old *Pæans* of Thaletas; and Athenæus likewise tells us, that the Spartans long continued to sing his airs; and according to the Scholiast on Pindar, this poet-musician was the first who composed the hyporchemes for the armed or military dance.

There was another poet and musician of the name of Thaletas, who was likewise a Cretan, that flourished much later than the cotemporary and friend of Lycurgus. Sir Isaac Newton has named him among the early victors at the Pythic games; and Dr Blair places him 673 years B. C. This is the Thaletas whom Plutarch makes cotemporary with Salom, and of whom it is related that he delivered the Lacedæmonians from the pestilence by the sweetness of his lyre.

THALIA, in Pagan mythology, one of the nine muses. She presided over Comedy; and is represented crowned with a garland of ivy, holding a mask in her hand, and wearing buskins on her feet.

THAMES, a celebrated river of England, being the largest in the island. The sources of this river are four rivulets, that rise in different parts of Cotswold hill in Gloucestershire, viz. the Lech, the Churne, and the Isis; these having touched Wiltshire, and joined their waters in one channel a little below Lechlade, a town on the borders of Oxfordshire, form a deep and copious stream, which there becomes navigable for very large barges, and is constantly, after it leaves this place, whatever poetical writers may pretend, called the *Thames*. Thence it proceeds into Oxfordshire; and having visited the city of Oxford, continues to divide that county from Berkshire; rolling by Abingdon, Wallingford, Reading, Henley, Maidenhead, Windsor,

Thamyris. Windfor, and fo to Staines, becoming there the boundary of the two counties of Middlefex and Surry; and having paffed by Chertsey and Kingfton in the latter, and Brentford in the former, it comes to the capital of the Britifh monarchy, London; and having travelled that imperial city, and her filter city of Weftminfter, purfues its courfe towards the fea: in its future progreff it divides Effex from Kent, vifiting in its paffage Deptford, Greenwich, Woolwich, Grays, and Gravend: at length it opens into the fea with a mouth between the Naze and the North Foreland, near fixty miles broad. In its paffage it receives no fewer than fix confiderable rivers that are not navigable, and eleven that are, which affords a vaft communication within land; its courfe has been computed about 140 miles, of which it is navigable near 100 from its mouth. In what is called the *Poff*, and which is properly the port of London, though, in the custom-house language, that is extended to the whole river below London bridge, has been known to lie upwards of 1000 fhips commodioufly; and it is univerfally allowed, that in no haven in Europe veffels lie more fafely, take in their ladings with greater eafe, or are delivered with fuperior dexterity and difpatch; fo that an immense commerce is carried on with fuch order and facility as moft aftonifhes thofe to whom it is moft thoroughly known and by whom it is beft underftood.

THAMYRIS, an ancient poet and mufician. He is called by Homer *Κίθαρις*, "one who fings to the cithara." Plutarch, in his Dialogue on Mufic, tells us that he was born in Thrace, the country of Orpheus, and had the sweeteft and moft fonorous voice of any bard of his time. Homer, in his catalogue of fhips, where he fpeaks of the cities under the dominion of Neftor, mentions Dorion as the place where Thamyris contended with the Mufes, whom he had the arrogance to challenge to a trial of fkill in poetry and mufic. The conditions and confequences of this contention are fully defcribed by the poet.

And Dorion, fam'd for Thamyris' difgrace,
Superior once of all the tuneful race,
'Till, vain of mortals empty praife, he ftrove
To match the feed of cloud-compelling Jove!
Too daring bard! whose unfeccful pride
Th' immortal Mufes in their art defy'd:
Th' avenging Mufes of the light of day
Depriv'd his eyes, and fnatch'd his voice away;
No more his heav'nly voice was heard to fmg,
His hand no more awak'd the filver ftring.

Paulanias informs us, that the painter Polygnotus, in his celebrated picture of Ulyffes's defcent into hell, which was preferved in the temple of Delphos, had represented the wretched Thamyris with his eyes put out, his hair and beard long and difhevelled, and his lyre, broken and unftring, lying at his feet. It is certain too, according to Paulanias, that this bard was not only the fubject of painting and poetry, but of fculpture; for he tells us, that among the ftatues with which mount Helicon was decorated, he faw one of Thamyris, represented blind, and holding a broken lyre in his hand.

According to Diodorus Siculus, he learnt mufic at the fchool of Linus; and if we may credit Suidas, he was generally regarded as the eighth among the epic poets who preceded Homer. As to his works, which are wholly loft, antiquity has preferved the names of

feveral. Tzetzes mentions a cosmogony, or creation of the world, in 500 verfes, and Suidas a theogony in 3000: perhaps both thefe writers fpeak of one and the fame poem. He was faid chiefly to have excelled in the compofition of hymns: on which account the fanciful philofopher Plato compares him with Orpheus; and as he makes the foul of this bard after death pafs into that of a fwan, he fixes the refidence of that of Thamyris in a nightingale. We only know his poem upon the War of the Titans by what Plutarch tells us of it from Heraclides of Pontus.

THANE, or THAIN, Thamur, a name of an ancient dignity among the Englifh and Scots, or Anglo-Saxons. Skene makes thane to be a dignity equal to the fon of an earl. Cambden will have it, that thanes were only dignified by the offices they bore. There were two kinds or orders of thanes; the king's thanes, and ordinary thanes. The firft were thofe who attended the king in his courts, and who held lands immediately of the king. The ordinary thanes, or the *thani minores*, were the lords of the manors, who had particular jurifdiction within their limits and over their own tenants; thefe changed their names for that of *barons*, and hence their courts are called *courts-baron* to this day.

THANET, an ifland of the county of Kent, furrrounded by the fea except on the north-eaft fide, where it is bounded by the branches of the river Stour, now inconfiderable to what they were formerly. It contains feveral villages, and the fea-port towns of Margate and Ramfden, and has the title of an earldom.

THAPSIA, the DEADLY CARROT; a genus of the dignity order, belonging to the pentandria clafs of plants. There are fix fpecies; the moft remarkable is the fœtida, with many pointed lobes, narrowed at their bafe. It is a native of Italy and Spain. The leaves are cut into many narrow fegments, almoft as fmall as thofe of the garden-carrot, but rough and hairy; their fegments are always oppofite, and are narrower at their bafe than at their points. The ftalks rife about two feet high, and are terminated by umbels of fmall yellow flowers, which appear in July: thefe are fucceeded by flat-bordered feeds, which ripen in the beginning of September. The roots of this fpecies were formerly ordered in medicine, but is now entirely difufed; a fmall dofe operating with extreme violence both upwards and downwards.

THAWING, the refolution of ice into its former fluid ftate by the warmth of the air. See FREEZING.

THEA, in botany. See TEA.

THEATINES, a religious order in the Romifh church, fo called from their principal founder John Peter Caraffa, then bifhop of Theate, or Chieti, in the kingdom of Naples, and afterwards pope, under the name of Paul IV. The names of the other founders were Gaetan, Boniface, and Configlieri. Thefe four pious men defiring to reform the ecclefiaftical ftate, laid the foundation of an order of regular clerks at Rome in the year 1524. Pope Clement VII. approved the inftitute, and permitted the brethren to make three religious vows, to elect a fuperior every three years, and to draw up ftatutes for the regulation of the order. They firft endeavoured, by their example, to revive among the clergy the poverty of the apoftles and firft difciples of our Saviour, and

were the first who assumed the title of *regular clerks*.

THEATRE, *theatrum*, in antiquity, a public edifice for the exhibiting of scenic spectacles or shows to the people; comprehending not only the eminence on which the actors appeared and the action passed, but also the whole area of the place common to the actors and spectators.

THEBAID, a celebrated heroic poem of Statius, the subject whereof is the civil war of Thebes, between the two brothers Eteocles and Polyneices; or, Thebes taken by Thebus.

THEBES, the name of a celebrated city of ancient Greece. It is supposed to have been built by Cadmus, about the year of the world 2555. This Cadmus, according to the Greeks, was the son of Agenor king of Sidon or of Tyre; but the Sidonians allow him to have been of no higher quality than his cook, and tell us that his wife was a musician at court, with whom he ran away into Greece. The Greek writers tell us, that being commanded by his father to go in search of his daughter Europa, whom Jupiter in the shape of a bull had carried off, and forbid to return without her, he built, or rebuilt, the city of Thebes, after having long sought her in vain. He was at first opposed by the Hyantes and Aones; the former of whom he defeated in battle, and forced them to retire into Locris: the latter submitted, and were incorporated among his subjects.

Those who endeavour to extract some truth from the multitude of fables in which the early part of the Grecian history is obscured, are of opinion that Cadmus was one of the Canaanites expelled by Joshua; and that he was of the family of the Cadmonites mentioned by Moses and Joshua. He is universally allowed to have introduced the Phœnician letters into Greece, set up the first schools, and introduced brass; which, from him, had the name of *Cadmean* given to it. The government of Thebes continued for a long time monarchical; and the names of a number of its kings have been transmitted to us, with some account of their transactions; but so much obscured by fable, that little or nothing can be determined concerning them. We shall therefore pass over this fabulous part of their history, and only take notice of that when the Thebans emerged from their obscurity, and for a time held the sovereignty of Greece.

Though the Thebans had been famed in the early period of their history for their martial achievements, yet in process of time they seem to have degenerated. At the time of the invasion of Xerxes, they were the first people in Greece who were gained over to the Persian interest. On account of this misbehaviour they were become very obnoxious to the other states, especially to the Athenians, whose power and renown increased every day, and threatened at last to swallow them up altogether. The Thebans being in no condition to oppose such a formidable power, put themselves under the protection of the Spartans, who, out of jealousy of the Athenians, readily forgave them; and so grateful were the Thebans for the kindness shewn them at this time, that during the whole of the Peloponnesian war Sparta had not a more faithful ally. By this means they not only recovered the government of Boeotia, of which they had been formerly in possession till deprived of it on account of their

fiding with the Persians, but their city became one of the first in Greece. By this prosperity the Thebans became so much elated, that, when the peace of Antalcidas came to be signed, they refused to come into it, as they were thus once more deprived of the government of Boeotia; so that it was not without the utmost difficulty that they were overawed into it by the other states. Not content with forcing them to give up this point, however, the Spartans undertook to change the form of Theban government, which at this time was a democracy, and accomplished through the treachery of those who had the care of the citadel.

The Thebans continued under the power of the Spartans for four years; at the end of which term a conspiracy being formed against them by some of the principal people in the city, among whom was a young nobleman named *Pelopidas*, the Spartans were massacred and driven out, and the citadel regained. During the tumult Epaminondas, afterwards the celebrated general, with a number of the best citizens, joined the party of Pelopidas; and the latter having called a general assembly of the Thebans, proclaimed liberty to them, and exhorted them in the strongest manner to fight for their country. This speech was received with the greatest acclamations; Pelopidas was unanimously proclaimed the preserver of Thebes, and was charged with the management of the war which was then to be declared against Sparta.

These transactions so much exasperated the Spartans, that they immediately sent their king Cleombrotus against them, though it was then the depth of winter. The Athenians, in the mean time, who had hitherto assisted the Thebans, declined any farther connection, lest they should draw upon themselves the resentment of the Spartans. However, they were soon after determined to act again on the same side, by an attempt which the Spartan general, Sphodrias, had rashly made on the Pyraum or harbour of Athens. Thus, by means of the Athenians, a powerful diversion was made in favour of the Thebans, who gradually recovered all the towns of Boeotia, and at length began to act offensively against their enemies, and made a powerful invasion in Phocis. They had now many sharp encounters with them; which, though they did not amount to decisive battles, yet did not fail to raise their courage, and distress that of the Spartans. In these encounters Pelopidas always signalized himself; and in the battle of Tanagra, where the Lacedæmonians were entirely defeated by the Athenians and their allies, Pelopidas had a principal share in the victory, and killed the Spartan general with his own hand. Soon after this, with a body of only 300 Thebans, he entirely routed and dispersed near 1000 Spartans: which was the greatest disgrace the latter had ever known; for till that time, whether in war with the Greeks or Barbarians, they had never been overcome by an equal, much less by such an inferior number of troops.

These successes of the Thebans greatly alarmed the Athenians, who continually sought to oppose their growing power. In this opposition they were joined by the Platæans, who by that means became extremely obnoxious to the Thebans, so that they at last came to a resolution to surprise their city. This they accomplished, and entirely destroyed it, together with

Thebes.

Thebes, another city extremely well affected to Athens. Soon after this, the Thebans, encouraged by their success, began to think of enlarging their territories, and making encroachments on their neighbours, as they saw other states had done before them. This spirit of conquest is said to have been raised by their general Pelopidas; in which he was seconded by Epaminondas, a person who, though like him endowed with all the necessary qualities to make a complete captain or patriot, had till then preferred a private life, and lived in a constant course of virtue and the study of philosophy. He had as yet seldom appeared in public, except to get himself excused from those state-employments which were so eagerly courted by others. This, however, had not hindered him from contracting an intimate friendship with Pelopidas, which had been daily improved by the correspondence of their tempers and principles, as well as by that zeal which both displayed for the good of their country; which last had made them, even before this time, appear together in action, and to such advantage, that Epaminondas's merit could be no longer concealed, nor indeed suffer him to continue longer in his beloved retirement: so that he saw himself, at length, deservedly placed at the head of the Theban troops; where he gave such early proofs of his future prowess and abilities, as justly gave him the next rank to Pelopidas. Both came now to be considered in the same light, as generals in the field, as governors at home, and as complete statesmen in the council. When the general treaty for restoring peace to Greece came to be proposed by the Athenians, and was upon the point of being executed by the rest of the states, the Thebans refused to agree to it, unless they were comprehended in it under the name of *Boeotians*. This demand was as strenuously opposed by the other contracting powers as insisted on by Epaminondas, who was there as ambassador on the part of the Thebans. Agefilas, in particular, told him in plain terms, that the Thebans ought to evacuate Boeotia, and leave the cities of it free and independent. To which he was answered by him, that the Lacedaemonians would do well to set them the example, by restoring Messenia to its ancient proprietors, and Laconia to its ancient freedom; for that the pretensions of the city of Thebes to Boeotia were as well founded, at least, as those of Sparta to those two countries. After this he went on, and showed how far Sparta had aggrandized herself at the expence of her neighbours: that peace might be indeed obtained, and upon a solid and lasting footing; but that this could not be otherwise done than by bringing all to an equality. This bold, though just remonstrance, in which not only Thebes, but Greece in general, was concerned, failed not, however, to exasperate the haughty Spartan monarch; and the Athenians, who had till now looked upon the Thebans as dependents either on them or on the Macedonians, were not a little offended to hear their ambassadors talk in such high terms. The result of the conference was, that Agefilas struck the name of *Thebes* out of the treaty and declared war against them, about the year 371 B.C.

The Spartans declare war against Thebes.

The Thebans were in no small consternation to see themselves engaged in a war with the powerful Spartans, without any ally to assist them; and the rest of the Grecian states having made peace with the latter,

began to look upon the ruin of the former as unavoidable. However, they resolved to make the best defence they could; and put their army under the command of Epaminondas, assigning him, at his own request, six others to act as counsellors or assistants. The Theban army consisted at most but of 6000 men, whereas that of the enemy was at least thrice that number; but Epaminondas trusted most in his horse, wherein he had much the advantage both in their quality and good management: the rest he endeavoured to supply by the disposition of his men, and the vigour of the attack. He even refused to suffer any to serve under him in the engagement, but such as he knew to be fully resolved to conquer or die. The two armies met at *Leuctra*, where the Spartans were defeated with great slaughter, as related under that article.

Thebes.

The victorious general, desirous to improve this great victory, sent an herald, crowned with garlands, to communicate it in form to the Athenians, in hopes that this would be an effectual means to re-unite them to the Theban interest. But it proved quite otherwise. Athens, which now looked upon them with a jealous eye, and had then in view the sovereignty of Greece, chose rather, if they could not wholly obtain it, to share it with Sparta, than to let the Thebans into the whole; and therefore declined even giving their herald audience. However, the Thebans took care to strengthen themselves by alliances; and, besides the Arcadians and Eleans, had got the Phocians, Locrians, Acarnanians, Euboeans, and other states, under their dependence: so that they were now in a condition to act offensively against the Spartans. Accordingly, under pretence of assisting the Arcadians, they entered Peloponnesus with a gallant army, with Epaminondas and Pelopidas at their head. Here they were joined by the Arcadian and other confederate forces; so that the whole amounted to 40,000, some say 50,000, men, besides great numbers of those who followed the camp, rather for plunder than fighting, and were computed about 20,000 more. The army was divided into four columns, and moved straight towards Sellasia, the place of their rendezvous, from which they pursued their march with fire and sword towards Sparta. But here they were repulsed by Agefilas, who was then returned to that metropolis.

To repair, in some measure, this disgrace, and at the same time to leave some lasting monument which should redound as much to his glory as to the mortification of the Spartans, Epaminondas left not their territories till he had restored the posterity of the old Messenians to their ancient dominions, out of which they had been banished near 300 years; rebuilt their capital, and left a strong garrison for its defence. He was, however, like to have been stopped in his return by Iphicrates, whom the Athenians had sent with 12,000 men to intercept him: but this last loitered so long at Corinth, that the Thebans had passed the defiles of Cenehræ, the chief place where he could have obstructed his retreat had he taken possession of it time enough. Epaminondas continued his march till he came in full view of the city of Corinth. However, he found the roads choked up with trees, rocks, stones, and every thing that could render them impassable; and the Corinthians well fortified, and resolute on a stout

defence. But he came so furiously upon them, notwithstanding all these difficulties, that they abandoned all their entrenchments and outworks to the Thebans, and fled into the city. Thither these pursued them sword in hand, and made an horrid slaughter of them; inasmuch that Corinth mult have unavoidably fallen into their hands, had their generals thought fit to pursue these advantages; but whether they were afraid of the Athenians falling upon them, or apprehended some dangerous ambush in a country with which they were but indifferently acquainted, or whether the army was too much weakened through so many fatigues, or lastly, whether the coldness of the season, it being then in the depth of winter, would not permit them to proceed far, they immediately marched towards Boeotia. This gave such a handle to their enemies, that they met with a very mortifying reception at their return to Thebes, where they were both arrested, and clapped up as state-prisoners, for having presumed to prolong their command four months longer than the time limited by law, which time took in almost the whole of their expedition from their first entrance into Peloponnesus. However, at last, the judges being ashamed to proceed any farther, they were both honourably acquitted.

20

das and Pe-
lopidas dis-
graced at
Thebes.

This prosecution had been chiefly carried on and encouraged by Menelides, a discontented Theban, and a bold and able speaker, who, by his artful calumnies at the trial, had so far prevailed with the judges as to get Epaminondas deprived of the government of Boeotia for a whole year, though he could not gain the same advantage against Pelopidas, who was a greater favourite of the people, as being his senior in point of time.

21
Warren-
ed with
Sparta.

By this delay the Spartans, with much difficulty, had recovered themselves from their great defeat at Leuctra, and settled their affairs in as good a posture as they could; but though they had repulsed the Thebans in Peloponnesus, yet, from the exploits they had performed there, especially in the dismembering the whole kingdom of Messenia from them, they had still cause to fear what their forces might do under two such generals; and had accordingly taken due care to strengthen themselves against them, and to provide themselves with a good number of auxiliaries from other states, especially from that of Athens, with whom they had renewed their old treaty, and had agreed that each should have the command five days alternately. Soon after this treaty, the Arcadians renewed the war, and took Pallene in Laconia by storm, put the garrison to the sword, and were presently assisted by the Argives and Eleans, and especially by the Thebans, who sent to them 7000 foot and 500 horse under the command of Epaminondas. This so alarmed the Athenians likewise, that they immediately sent Gobrias with some forces to oppose his passage in good earnest; and he so behaved himself against the Thebans, that they were forced to abandon Peloponnesus a second time. This ill success gave fresh occasion to the enemies of Epaminondas to blame his conduct in the highest terms, notwithstanding the singular bravery with which he and his troops had forced the pass. Even his friends could not but suspect him of partiality for the Spartans, in not pursuing his advantage over them, and making a

21
The The-
bans re-
pulsed.

greater slaughter of them when he had it in his power; whilst his enemies made it amount to no less than treachery to his country: so that their brave general was once more deprived of the government of Boeotia, and reduced to the condition of a private man. He did not continue long under this disgrace, before an occasion offered to make his services again of such necessity to the state, as to give him an opportunity to retrieve his fame, and wipe off the stain which his enemies had thrown upon him.

The Thessalians, who had groaned some time under the tyranny of the usurper Alexander furnished the Phœrean, sent an embassy to Thebes, to implore their aid and protection: upon which Pelopidas was immediately sent as ambassador, to expostulate with him on their behalf. He was then in Macedonia, from whence he took the young prince Philip, afterwards the celebrated monarch, in order to protect and educate him; and, upon his return, marched directly to Pharsalus in Thessaly, in order to punish the treachery of some mercenaries, who had deserted the Thebans in that expedition; but when he came thither, he was surprised to be met by the tyrant at the head of a numerous army before that city, whilst his own was but as an handful of men in comparison of it. However, whether he supposed, or would be thought to do so, that Alexander came thither to justify himself, and answer to the complaints alleged against him, he went, with Ismenias his colleague, to him unarmed and unattended, not doubting but his character as ambassador from so powerful a republic, joined to his own character and authority, would protect them from insult or violence: but he found himself mistaken; for Alexander had no sooner got them in his hands, than he caused them to be seized, and sent prisoners to Phœre.

The Thebans, highly resenting the indignity offered to their ambassadors, sent immediately an army into Thessaly: but the generals were repulsed with great loss by the Phœrean usurper; and it was owing to Epaminondas, who was among them only as a private sentinel, that they were not totally cut off. For the Thebans, finding themselves in such imminent danger, which they attributed to the incapacity of their generals, had immediately recourse to him, whose valour and experience had been so often tried; and, partly by persuasions and intreaties, and partly by threats, obliged him to take the command. This soon gave a different turn to their affairs, and converted their flight into a safe and regular retreat; for he took the horse and light-armed foot, and placed himself at their head in the rear, and charged the enemy with such vigour and bravery, that he obliged them to desist from their pursuit.

However, as the army had suffered such loss before as not to be sufficient to pursue them in their turn, he was obliged to return with them to Thebes, with their pusillanimous generals; where the latter were fined 12,000 drachms each, and the former was reinstated in the command, and sent with a new reinforcement to repair the late dishonour, and prosecute their revenge. The news of his being in full march on this errand, greatly alarmed the tyrant: but Epaminondas, preferring the safety of his imprisoned colleague to all other considerations, forbore pushing hostilities to extremes,

for fear of provoking the enemy to wreak all his fury on him: to prevent which, he contented himself for a while hovering about with his army, and now-and-then with such slight skirmishes as should intimidate the tyrant, and bring him the sooner to make some satisfactory offers. Alexander being fully convinced of the superiority of the Theban general, was glad to accept of a truce of 30 days, and to restore Pelopidas and Himenias to him; upon which he immediately withdrew his forces, and returned with them to Thebes.

By this time Thebes was raised to a sufficient height of reputation and glory to begin to aim in earnest at the sovereignty of Greece in her turn. The main obstacle to it was, that the other states grew so jealous of her present greatness, as to enter into the strongest alliances and confederacies to prevent its farther growth; so that not being able now to procure many allies at home, they made no difficulty to seek for them abroad; and the Lacedæmonians, by leading the van, gave them a plausible pretence to follow their steps, and to procure an alliance with Persia, which at that time they found was ready to accept of the offers on any terms; the only question was, which of the three states should be preferred, Sparta, Athens, or Thebes. At the same time the Thebans proposed to their few confederates to send likewise proper deputies to the Persian court, in order to support their respective interests; which they readily agreed to. These were the Arcadians, Eleans, and Argives; at the head of whose deputation Pelopidas was sent on the behalf of the Thebans; which the Athenians being apprised of, appointed two on their part. These being all arrived at the Persian court, began to pursue each their respective interests; but Pelopidas had by that time gained such credit there, both for his singular address and his extraordinary exploits, that he was distinguished in a particular manner from all the other deputies, and was received by the king with the most manifest marks of honour and esteem, who freely owned himself convinced that the Thebans were the people on whom he could most safely depend; and after having greatly applauded the equity of his demands, ratified and confirmed them with great readiness, to the no small mortification of the other states. The substance of them was, that the liberties formerly granted to the other towns of Greece should be confirmed; that Messenia, in particular, should continue free and independent on the jurisdiction of Sparta; that the Athenians should lay up their fleet; and that the Thebans should be looked upon as the ancient and hereditary friends of Persia.

The Thebans took advantage of the dissensions which prevailed among the Greeks as a pretence for increasing their forces; and Epaminondas thought it a proper opportunity for his countrymen to make a bold effort to obtain the dominion at sea, as they had obtained it in a great measure at land. He proposed it to them in a public assembly, and encouraged their hopes from the experience of the Lacedæmonians, who in Xerxes's time had, with ten ships only at sea, gained the superiority over the Athenians, who had no fewer than 200; and added, that it would be a disgrace now to Thebes to suffer two such republics to engross the empire of so extensive an element, without putting in at least for their share of it. The people

Vol. X.

2

readily came into his proposal, not without extraordinary applause, and immediately ordered 100 galleys to be equipped; and in the mean while sent him to Rhodes, Chios, and Byzantium, to secure those states in their interest, and get what assistance he could from them. His negotiations had all the success that could be wished for, notwithstanding the strenuous opposition of the Athenians, and of their admiral Laches, who was sent with a powerful squadron against him. But what more effectually thwarted all his measures, was the work that they found for him at land, and the obliging the Thebans to take part in the quarrels that then reigned among their neighbours: so that whatever projects they had concerted, proved abortive for the present; and the death of Epaminondas, which happened not long after, put an effectual stop to them.

During the absence of that general, and of his colleague Pelopidas, the Orchomenians, being spirited up by some Theban fugitives, had formed a design to change the Theban government into an aristocracy; and 300 horsemen of the former had been actually sent to put it in execution. Their project, however, was timely discovered by the vigilance of the magistrates, who caused them to be seized, and put immediately to death. They next sent a sufficient force against the city of Orchomenos, with orders to put all the men to death, and to sell the women and children for slaves, which was punctually done; after which they raised that noble city to the ground. Pelopidas was then on his way to Thebally, at the head of a powerful army, whither he had been sent to assist the Thebans, who still groaned under the tyranny of Alexander the Phæzean, and had made several brave efforts to recover their liberty, but had been still overpowered by that usurper. Being joined by the Thebans, he encamped in the face of the enemy, though far superior in number, and consisting of above 20,000 men. A fierce engagement soon ensued, in which both sides fought with uncommon bravery. The place where the battle was fought was called *Cyncephalea*, from several little hills on it, between which there ran a large plain. Both sides endeavoured at first to post themselves on these eminences with their foot, whilst Pelopidas ordered his cavalry to charge that of the enemy below; which they did with such success, that they soon put them to the rout, and pursued them over the plain. This obliged the tyrant to gain the tops of the hills, where he greatly annoyed the Thebans that endeavoured to force those ascents; so that Pelopidas was obliged to give over his pursuit to come to their relief. This immediately inspired the Thebans with fresh courage, who began again to charge the enemy at several onsets; and soon threw them into such disorder, that they were forced to give way. Pelopidas no sooner perceived the advantage, than he began to look about for Alexander, with a design of engaging him. Having found him out as he was commanding his right wing and endeavouring to rally his men, he moved directly to him; and being got near enough to be heard by him, challenged him to decide the battle by single combat with him. Alexander, instead of accepting the offer, turned about, and with all the speed he could ran to screen himself amongst his guards. Upon this Pelopidas charged him with such furious speed, that he obliged him to retire farther, and shelter himself within the thickest

rank; the fight of which made him attack with fresh vigour, and fight more desperately against him. He tried in vain several times to break through their ranks to reach him, cutting down great numbers of those that came forward to oppose him: his eagerness at length exposed him so far to the darts that were shot at him at a distance, that some of them went quite through his armour, and gave him a desperate wound or two, while the rest advanced and stabbed him in the breast with their spears.

Is killed.

It is scarce possible for words to express the grief and despair which not only his brave Thebans, but likewise the Thessalians and other allies, showed at the sight of their slain general: some of the latter, who had perceived the danger he was exposed to, came down the hill with all possible speed to his relief; but when they perceived that they were come too late to save him, both they and the rest of the little army thought on nothing but how to revenge his death. They rallied accordingly, both horse and foot, as quick as possible, and began to charge the enemy afresh, and with such desperate fury, that they at length gained a complete victory over them, and killed above 3000 of them in their pursuit, besides a much greater number which they had slain on the field of battle, though they still looked upon all these advantages as vastly too small to compensate the loss of their brave general.

The news of his death had no sooner reached Thebes than the whole city was seen in as deep a mourning as his army. However, they sent a reinforcement to it of 7000 foot and 700 horse, as well to revenge the death of that general, as to improve the victory he had gained over the enemy; by the help of which they fell so furiously on them, that they quickly broke and totally defeated the shattered remains of Alexander's army. Hereupon he was forced to sue for peace, and to accept it on such conditions as the conquerors thought fit to impose. He was at length dispatched in his bed by his wife Thebe, assisted by her brothers, about seven years after his defeat. His body was afterwards dragged along the streets, trodden under foot, and left a prey to the dogs.

34
And at last murdered.

35
Ambition of the Thebans.

All this while the Thebans were watching to improve every commotion that happened, every success they met with, to the forwarding of their then reigning and favourite project of increasing their power above all the rest, and in their turn to give laws to Greece. Their late success in Theffaly, and the rupture between the Arcadians and Mantineans at the same time about some consecrated money which the former had taken out of the temple of Olympias to pay their troops employed against the Eleans, and which the latter called a downright sacrilege, besides other disorders that reigned in the other states of Greece, gave fresh encouragement to Thebes to set up for arbiters in those disputes; and so much the more, as those who had embezzled the sacred money, and wanted rather to embroil matters than to have them brought to light, sent that republican word that the Arcadians were just upon the point of revolting to the Spartans, and advised them to come and put an immediate stop to it. At the same time they dispatched some private directions to a Theban officer in Tegea to apprehend several of their own people as disturbers of the peace: which was accordingly done, and several eminent persons were confined as prisoners of state; but were soon after dischar-

ged, and loud complaints were made against such arbitrary and unjust proceedings. The officer was accused before the Theban senate for having intermeddled in their affairs, and endeavoured to interrupt the good correspondence between the two states. It was even insisted on by some of the Teggans, that he should be indicted and proceeded against by his principals; whilst the more moderate sort, who foresaw the consequences that were like to attend such appeals, and that it would infallibly bring the Thebans upon them, loudly protested against their marching into their territories, and did all they could to prevent it. The Thebans, however, were become too powerful and ambitious to miss so fair an opportunity of getting once more footing in Peloponnesus, as they had long ago premeditated; and Epaminondas was so far from making a secret of their design, that he told the Arcadian deputies in justification of it, that as it was on their account that the Thebans engaged in the war, they had acted treacherously with them in making peace with Athens without their consent: however, that when he was got with his army on his march into Peloponnesus to assist his friends, he would soon see what proofs they, the Arcadians, would then give of their fidelity. This speech did not fail to alarm them greatly; especially as it was spoken in such a magisterial style and threatening tone. Even those who were best affected to the Thebans could not forbear expressing their dislike of it; and all that had the welfare of Peloponnesus at heart, readily agreed with the Mantineans, that there was no time to be lost to use all proper means to prevent the impending storm.

36
Epaminondas displays the states of Greece.

Athens and Sparta were accordingly applied to, and were easily prevailed upon to assist the Mantineans, and to come into a strict confederacy against the Thebans; and to prevent all disputes about the command of the army, it was agreed that each state should have it in its own territories; which plainly shows how terrified they all were at the apprehension of a fresh invasion of the Thebans: for this was a point which neither the Spartans nor Athenians would have so readily given up to the Arcadians, though these had formerly as strenuously insisted upon it, even when they were almost reduced to the last extremity, and had never been able to obtain it till now. But Epaminondas was then in full march at the head of his Boeotian troops, with some Euboean auxiliaries and a body of stout Theffalian horse; and was moreover to be joined by the Messenians, Argives, and several other nations, as soon as he had entered Peloponnesus. The confederate army against him had ordered their rendezvous at Mantinea, the place which they naturally concluded would be first attacked, as being the chief seat of those who had revolted from the Thebans. But whilst they were securing themselves on that side, Epaminondas, who wisely considered how far this confederacy and expedition must have drained the city of Sparta of its chief strength, broke up privately from Nemæa, where he had lain for some time encamped, and marched all that night with a design to have surprised that important capital: but his project being timely discovered, the vigilant king took care to disconcert it; so that, though the Theban general made several vigorous assaults on that city, he was so stoutly repulsed, and the Spartans behaved with such intrepid valour, that he was forced to retire and turn his thoughts against Mantinea,

which he judged by this time to have been quite defenceless. He judged rightly indeed; for the place was not only drained of its troops, but likewise of its inhabitants, who took that opportunity whilst the scene of war was in Lacedæmon, to gather in their harvest, and were scattered all over the country; so that he would not have met with any difficulty in gaining the town, had not the Athenian auxiliaries come unexpectedly to its relief and given him a fresh repulse.

These two last defeats greatly exasperated the Theban general, who had never till now been used to them, and could not but foresee that they would not only lessen his reputation with his allies, but, if not timely retrieved, would fully the glory of all his former exploits. What added to his present difficulties was, that the time allotted him for his expedition was almost expired; so that he had but a short space left to undertake some brave achievement, which might recover his and his country's honour, and keep up the spirits of his auxiliaries and those under his protection. He was moreover got very far into the enemy's country, and saw plainly enough how narrowly they watched all his motions, and how well prepared they were to oppose him whatever attempt he resolved upon, whether to attack them or to retreat. Under all these difficulties, he rightly considered, that he must immediately resolve upon a decisive battle; in which, if his pristine fortune followed him, he might at once retrieve his affairs, and make himself master of Peloponnesus; or, if that failed him, as it lately had done, fall honourably in the attempt. In this engagement Epaminondas made the wisest disposition of his troops, attacked and fought with the most intrepid courage and conduct, and had opened himself a way through the Spartan phalanxes, thrown them into the utmost confusion, and made a terrible slaughter of them, inasmuch that the field of battle was covered with their wounded and slain, when, in the heat of the fight, having ventured himself too far in order to give them a total overthrow, the enemy rallied again, pouring their whole fury and three whole volleys of darts at him, some of which he drew out and returned to them, till at length, being covered with wounds, and weakened with the loss of so much blood, he received a mortal wound from a javelin, and was with great difficulty rescued from the enemy by his brave Thebans, and brought alive, though speechless, into his tent. As soon as he had recovered himself, he asked his friends that were about him what was become of his field; and being told that it was safe, he beckoned to have it brought to him, and killed it. He next inquired which side had gained the victory; and being answered, The Thebans; he replied, Then all is well: and upon observing some of his friends bewailing his untimely death, and leaving no children behind him, he is said to have answered, Yes; I have left two fair daughters, the victory of Leuctra, and this of Mantineæ, to perpetuate my memory. Soon after this, upon the drawing of the point of the javelin out of his body, he expired.

The consequence of this great general's fall, and of this bloody fight, in which neither side could boast any great advantage over the other, but a great loss of men on both sides, inasmuch that Xenophon makes it a drawn battle, was, that both parties agreed on a cessation of arms, and parted as it were by consent, to

take care of their wounded and slain. The Thebans indeed thus far gained the greater share of glory, that they renewed the fight; and after a most desperate contest, gained the victory over those Spartans that opposed them, and rescued the body of their dying general out of their hands. However, an effectual end was put to this bloody war, and a general peace agreed on by all but Sparta; who refused it only because the Mælians were included in it. But as to the Thebans, they had no great reason to boast of this dear-bought victory, since their power and glory began to decline from that very time; so that it may be truly said, that it rose and set with their great general.

On the death of Epaminondas, the Thebans relapsed into their former state of inactivity and indolence; and at last having ventured to oppose Alexander the Great, their city was taken, and the inhabitants slaughtered for several hours, after which the buildings were destroyed. It was rebuilt by Cassander, but never afterwards made any considerable figure among the states of Greece. About the year 146 B. C. it fell under the power of the Romans, under which it continued till the extinction of their empire by the Turks. It is now called *Thive*, and is nothing to what it was formerly; yet it is four miles in circumference, but so full of ruins, that there are not above 4000 Turks and Christians in it. It is now famous for a fine sort of white clay, of which they make bowls for pipes after the Turkish fashion. They are never burnt, but dry naturally, and become as hard as a stone. There are two mosques in Thebes, and a great many Greek churches. It is seated between two small rivers, in E. Long. 24. 5. N. Lat. 38. 22.

THEBES is also the ancient name of the capital of Upper Egypt, named likewise *Hecatompolis* and *Disopolis*. It was celebrated for its grandeur, and among other things, for its having 100 gates. It is now inconsiderable; but there are vast columns of marble and porphyry lying half buried in the ground, with statues and obelisks of a prodigious size, inscribed with hieroglyphics. Not far from this place are to be seen the sepulchres of the kings of Thebes, lying in grottoes, cut out of the rock in a most beautiful manner, with long rooms or galleries under the mountains. The modern name of the place is *Sayd*.

THEFT, or *Simple LARCENY*, is "the felonious taking and carrying away, of the personal goods of another." This offence certainly commenced then, whenever it was, that the bounds of property, or laws of *meum* and *tuum*, were established. How far such an offence can exist in a state of nature, where all things are held to be common, is a question that may be solved with very little difficulty. The disturbance of any individual, in the occupation of what he has seized to his present use, seems to be the only offence of this kind incident to such a state. But, unquestionably, in social communities, when property is established, any violation of that property is subject to be punished by the laws of society; though how far that punishment should extend, is matter of considerable doubt.

By the Jewish law, it was only punished with a pecuniary fine, and satisfaction to the party injured. And in the civil law, till some very late constitutions, we never find the punishment capital. The

Theft.

laws of Draco at Athens punished it with death : but his laws were said to be written in blood ; and Solon afterwards changed the penalty to a pecuniary mulct. And so the Attic laws in general continued ; except that once, in a time of dearth, it was made capital to break into a garden and steal figs : but this law, and the informers against the offence, grew so odious, that from them all malicious informers were styled *syco-phants* ; a name which we have much perverted from its original meaning. From these examples, as well as the reason of the thing, many learned and scrupulous men have questioned the propriety, if not lawfulness, of inflicting capital punishment for simple theft. And certainly the natural punishment for injuries to property seems to be the loss of the offender's own property : which ought to be universally the case, were all mens fortunes equal. But as those who have no property themselves are generally the most ready to attack the property of others, it has been found necessary, instead of a pecuniary to substitute a corporal punishment ; yet how far this corporal punishment ought to extend, is what has occasioned the doubt. Sir Thomas More and the marquis Beccaria, at the distance of more than two centuries, have very sensibly proposed that kind of corporal punishment which approaches the nearest to a pecuniary satisfaction, viz. a temporary imprisonment, with an obligation to labour, first for the party robbed, and afterwards for the public, in works of the most slavish kind ; in order to oblige the offender to repair, by his industry and diligence, the depredations he has committed upon private property and public order. But, notwithstanding all the remonstrances of speculative politicians and moralists, the punishment of theft still continues throughout the greatest part of Europe to be capital : and Puffendorf, together with Sir Matthew Hale, are of opinion that this must always be referred to the prudence of the legislature ; who are to judge, say they, when crimes are become so enormous as to require such sanguinary restrictions. Yet both these writers agree, that such punishment should be cautiously inflicted, and never without the utmost necessity.

The Anglo-Saxon laws nominally punished theft with death, if above the value of twelvepence : but the criminal was permitted to redeem his life by a pecuniary ransom ; as, among their ancestors the Germans, by a stated number of cattle. But in the ninth year of Hen. I. this power of redemption was taken away, and all persons guilty of larceny above the value of twelvepence were directed to be hanged ; which law continues in force to this day. For though the inferior species of theft, or petit larceny, is only punished by whipping at common law, or, by statute 4 Geo. I. c. 11. may be extended to transportation for seven years, as is also expressly directed in the case of the Plate-glass Company, yet the punishment of grand larceny, or the stealing above the value of twelvepence, (which sum was the standard in the time of king Athelstan, 800 years ago) is at common law regularly death : which, considering the great intermediate alteration in the price or denomination of money, is undoubtedly a very rigorous constitution ; and made Sir Henry Spelman (above a century since, when money was at twice its present rate) complain, that while every thing else

was risen in its nominal value, and become dearer, the life of man had continually grown cheaper. It is true, that the mercy of juries will often make them shun a point, and bring in larceny to be under the value of value or twelvepence, when it is really of much greater value : but this, though evidently justifiable and proper when it only reduces the present nominal value of money to the ancient standard, is otherwise a kind of pious perjury, and does not at all excuse our common law in this respect from the imputation of severity, but rather strongly confesses the charge. It is likewise true, that by the merciful extensions of the benefit of clergy by our modern statute-law, a person who commits a simple larceny to the value of thirteen pence or thirteen hundred pounds, though guilty of a capital offence, shall be excused the pains of death : but this is only for the first offence. And in many cases of simple larceny the benefit of clergy is taken away by statute : as from horse-stealing in the principals and accessories both *before* and *after* the fact ; theft by great and notorious thieves in Northumberland and Cumberland ; taking woollen cloth from off the tenters, or linens, fustians, calicoes, or cotton, goods, from the place of manufacture ; (which extends, in the last case, to aiders, assisters, procurers, buyers, and receivers) ; feloniously driving away, or otherwise stealing one or more sheep or other cattle specified in the acts, or killing them with intent to steal the whole or any part of the carcase, or aiding or assisting therein ; thefts on navigable rivers above the value of forty shillings, or being present, aiding, and assisting thereat ; plundering vessels in distress, or that have suffered shipwreck ; stealing letters sent by the post ; and also stealing deer, hares, and conies, under the peculiar circumstances mentioned in the Waltham black act. Which additional severity is owing to the great malice and mischief of the theft in some of these instances ; and, in others, to the difficulties men would otherwise lie under to preserve those goods, which are so easily carried off. Upon which last principle the Roman law punished more severely than other thieves the *Abigei*, or stealers of cattle ; and the *Balnearii*, or such as stole the cloaths of persons who were washing in the public baths ; both which constitutions seem to be borrowed from the laws of Athens. And, so too, the ancient Goths punished with unrelenting severity thefts of cattle, or of corn that was reaped and left in the field : such kind of property (which no human industry can sufficiently guard) being esteemed under the peculiar custody of heaven.

THEFT-Bole, (from the Saxon *theof*, i. e. *sur*, and *bote*, *compensatio*) is the receiving of a man's goods again from a thief, after stolen, or other amends not to prosecute the felon, and to the intent the thief may escape ; which is an offence punishable with fine and imprisonment, &c.

THEME, denotes the subject of an exercise for young students to write or compose on.

THEMISON, a physician of Laodicea, a disciple of Asclepiades. He founded the methodic sect, with a view to the more easily teaching and practising the art of medicine. See **MEDICINE**, n° 78.—80. Themison gave the first account of diacodium, which was prepared of the juice and decoction of poppy-heads and honey.

Theft

Theodore.

Theodore.

THEMISTIUS, an ancient Greek orator and philosopher, a native of Paphlagonia, who flourished in the fourth century. He had great interest and favour with the emperors in his time, and though a heathen, was of a very tolerating spirit. He taught for many years at Constantinople, of which city he was made præfect by Julian and Theodosius; and lived to be exceeding old. More than 30 of his orations are still extant, beside commentaries on several parts of Aristotle's works.

THEMISTOCLES, the renowned Athenian admiral, general, and patriot, who gained the battle of Salamine against the Persians. Being banished his country by his ungrateful fellow-citizens, he fled to Artaxerxes king of Persia; but, in order to avoid taking up arms against his country, he flew himself, 464 B. C. See ATTICA, n° 76, *et seq.*

THEOBALD (Lewis), the son of an attorney at Sittingbourn in Kent, was a well-known writer and critic in the early part of the present century. He engaged in a paper called the *Censor*, published in Milt's Journal, wherein, by delivering his opinions with too little reserve concerning some eminent wits, he exposed himself to their resentment. Upon the publication of Pope's Homer, he praised it in terms of extravagant admiration, yet afterwards thought proper to abuse it as earnestly; for which Pope at first made him the hero of his Dunciad, though he afterward laid him aside for another. Mr Theobald not only exposed himself to the lashes of Pope, but waged war with Mr Dennis, who treated him more roughly, though with less satire. He nevertheless published an edition of Shakespeare, in which he corrected with great pains and ingenuity many faults that had crept into that poet's writings. This edition is still in great esteem; being in general preferred to those published by Pope, Warburton, and Hanmer. He also wrote some plays, and translated others from the ancients.

THEOCRACY, in matters of government, a state governed by the immediate direction of God alone: such was the ancient government of the Jews before the time of Saul.

THEOCRITUS, a celebrated Greek poet, was born at Syracuse, but lived at the court of Egypt in the reign of Ptolemy Philadelphus, about the 285th year before the Christian æra. It is said that at his return to Syracuse, venturing to speak ill of Hiero king of that city, he was put to death by his order. There are still extant Theocritus's Idylliums in the Doric dialect, which are masterpieces in their kind, written with admirable simplicity, and filled with inexpressible beauties. The best edition of them is that of Oxford, in 1699, 8vo.

THEODICY. See METAPHYSICS, n° 6. 222—230.

THEODOLITE, a mathematical instrument much used in surveying. See GEOMETRY.

THEODORE, king of Corsica, baron Nieuhoff in the county of La Marc in Westphalia. He had his education in the French service, and afterwards went to Spain, where he received some marks of regard from the duke of Riparda and cardinal Alberoni; but being of an unsettled disposition, he quitted Spain, and

travelled into Italy, England, and Holland, in search of some new adventure. He at last fixed his attention on Corsica, and formed the scheme of rendering himself sovereign of that island. He was a man of abilities and address; and having fully informed himself of every thing relating to Corsica, went to Tunis, where he fell upon means to procure some money and arms; and then went to Leghorn, from whence he wrote a letter to the Corsican chiefs, Giasteri and Paoli, offering considerable assistance to the nation if they would elect him as their sovereign. This letter was consigned to count Domenico Rivarola, who acted as Corsican plenipotentiary in Tuscany; and he gave for answer, that if Theodore brought the assistance he promised to the Corsicans, they would very willingly make him king.

Upon this he without loss of time set sail, and landed at Tavagna in the spring of the year 1736. He was a man of a very stately appearance, and the Turkish dress he wore added to the dignity of his mien. He had a few attendants with him; and his manners were so engaging, and his offers so plausible, that he was proclaimed king of Corsica before count Rivarola's dispatches arrived to inform the chiefs of the terms upon which he had agreed. He brought with him about 1000 zechins of Tunis, besides some arms and ammunition, and made magnificent promises of foreign assistance; whence the Corsicans, who were glad of any support, willingly gave into his schemes. Theodore instantly assumed every mark of royal dignity. He had his guards and his officers of state. He conferred titles of honour, and struck money both of silver and copper. The silver pieces were few in number, and can now hardly be met with; the copper coins have on one side T. R. that is, "Theodorus Rex," with a double branch crossed, and round it this inscription, PRO BONO PUBLICO RE. Co. that is, "For the public good of the kingdom of Corsica;" on the other side is the value of the piece; *Cinque Soldi*, or five sous.

The Genoese were not a little confounded with this unexpected adventurer. They published a violent manifesto against Theodore, treating him with great contempt; but at the same time showing they were alarmed at his appearance. Theodore replied, in a manifesto, with all the calmness and dignity of a monarch; but after being about eight months in Corsica, perceiving that the people began to cool in their affections towards him, he assembled his chiefs, and declared he would keep them no longer in a state of uncertainty, being determined to seek in person the support he so long expected. He settled an administration during his absence, recommended unity in the strongest terms, and left the island with reciprocal assurances of fidelity and affection. He went to Holland, where he was so successful as to obtain credit from several rich merchants, particularly Jews, who trusted him with cannon and other warlike stores to a great value, under the charge of a supercago. With these he returned to Corsica in 1739; but by this time the French, as auxiliaries to the Genoese, had become so powerful in the island, that though Theodore threw in his supply of warlike stores, he did not incline to venture his person, the Genoese having set a high price on his head. He therefore again departed; and after many unavailing attempts

Theodore, attempts to recover his crown, at length chose for retirement a country where he might enjoy the participation of that liberty which he had so vainly endeavoured to give his Corsicans; but his situation in England by degrees grew wretched, and he was reduced to low as to be several years before his death a prisoner for debt in the King's bench. At length, to the honour of some gentlemen of rank, a charitable contribution was set on foot for him in the year 1753. Mr Boswell observes, that Mr Horace Walpole generously exerted himself for the unhappy Theodore, and wrote a paper in the World with great elegance and humour, soliciting a contribution for the unhappy monarch in distress, to be paid to Mr Robert Doddsley bookseller, as lord high treasurer. This brought him a very handsome sum, and he was allowed to get out of prison. That gentleman adds, that Mr Walpole has the original deed, by which Theodore made over the kingdom of Corsica in security to his creditors, and that he has also the great seal of the kingdom. Theodore died in 1756, and was buried in St Anne's church-yard, Westminster; where, in 1757, a simple unadorned monument of marble was erected to his memory by a gentleman, with an inscription, which, after mentioning some of the above particulars, concludes with the following lines:

The grave, great teacher, to a level brings
 Heroes and beggars, galley-slaves and kings:
 But Theodore this moral learn'd ere dead,
 Fate pour'd its lesson on his living head,
 Bestow'd a kingdom and deny'd him bread.

Theodore left a son, who is an accomplished young gentleman.

THEODORET, bishop of St Cyrius in Syria, in the 5th century, and one of the most learned fathers of the church, was born in the year 386, and was the disciple of Theodorus Mopsuestia and St John Chrysostom. Having received holy orders, he was with difficulty persuaded to accept of the bishopric of St Cyrius, about the year 420. He discovered great fru-

gality in the expences of his table, dress, and furniture, but spent considerable sums in improving and adorning the city of Cyrius. He erected two large bridges, public baths, fountains, and aqueducts, and laboured with great zeal and success in his diocese. Yet his zeal was not confined to his own church: he went to preach at Antioch, and the neighbouring towns; where he became admired for his eloquence and learning, and had the happiness to convert multitudes of people. He wrote in favour of John of Antioch and Nestorius, against Cyril's Twelve Anathemas: he afterwards attacked the opinions of Nestorius, and was deposed in the synod held by the Eutychians at Ephesus; but was afterwards restored by the general council of Chalcedon, in which he was present, in 451. It is thought that he died soon after; though others say that he lived till the year 470. There are still extant Theodore's excellent Commentary on St Paul's Epistles, and on several other books of the holy Scriptures. 2. His Ecclesiastical History from the time of Arius to Theodosius the Younger. 3. The history of the famous Anchorites of his time. 4. Epistles. 5. Discourses on Providence. And, 6. An excellent treatise against the Pagans, intitled, *De curandis Græcorum affectibus*; and other works. The best edition of all which is that of Father Sirmond in Greek and Latin, in 4 vols folio.

THEODOSIUS I. called the Great, was a native of Spain. The valour he had shown, and the great services he had done to the empire, made Gratian, attacked by the Goths and Germans, to admit him as a partner in the government. He received the purple in 379, aged 43. See CONSTANTINOPLE, n° 81—92.

THEOGNIS, an ancient Greek poet of Megara in Achaia; flourished about the 59th Olympiad, 144 B. C. We have a moral work of his extant, containing a usual summary of precepts and reflections, to be found in the collections of the Greek minor poets.

T H E O L O G Y;

Or, The Study of RELIGION.

TO ascend by a chain of reasoning from things visible to things invisible, from palpable to impalpable, from terrestrial to celestial, from the creature even up to the Creator, is the business of theology: it is not surprising, therefore, that the union of many doctrines is necessary completely to form such a science. To understand, and properly to interpret, the scriptures or revelation, demands not less sagacity than assiduity. The gift of persuasion is also essential to the ministers of the gospel. And lastly, the civil government has committed to their care certain functions of society, which relate, or seem to relate, either to the doctrines or morality of the gospel. They assemble, for example, in bodies to form consistories; they judge in matrimonial cases; they carry consolation and hope to the souls of the sick; they prepare for death those criminals which justice sacrifices to public safety; they take upon themselves the charge of Ephori, with the inspection of some pious foundations: they distribute

alms; they administer the sacraments, &c.

To discharge fully so many duties, the theologian has need, 1. Of several preparatory studies; 2. Of some theoretic sciences; and, 3. Of many doctrines which have for their object his ministerial office. The first are,

1. The languages; and among these,
 - (a) His native language, in which he is to preach and exercise his ministry, and with which he ought to be perfectly acquainted.
 - (b) The Latin language, which is the language of the learned world in general.
 - (c) The Greek language, in order to understand the new Testament.
 - (d) The Hebrew language, of which the Talmudian and Rabbinical idioms are a part.
 - (e) The Arabic language.
 - (f) The Syriac language.
 - (g) The French language. And,

(h) The

(b) The English language. The two latter of which now appear necessary to every man of letters, and particularly to a theologian, on account of the excellent works which are wrote in those languages.

2. The principal parts of philosophy; as;

(a) Logic.

(b) Metaphysics.

(c) Moral philosophy.

3. Rhetoric and eloquence, or the art of speaking correctly, of writing with elegance, and of persuasion.

To which may be added,

4. The elements of chronology, and universal history.

5. The study of the Jewish antiquities.

He who would devote himself to the important employment of a theologian, and has the noble ambition to excel in it, should early impress on his mind these truths: that the years which are passed at an university are few; that they run rapidly away; that they are entirely engrossed by the theoretic sciences; and that he who does not carry with him to the university a fund of knowledge in the preparatory parts of learning, commonly brings very little away, when his age or his parents oblige him to quit it.

The theoretic sciences of a theologian are,

1. The dogmatic, or the theory of theology; which some Latin authors name *alio thetica*, or *systematica*.

2. The exegesis, or the science of attaining the true sense of the holy scriptures.

3. The hermeneutic, or the art of interpreting and explaining the scriptures to others. This differs in general but little from the exegesis, and in some respects is quite the same.

4. Polemic theology, or controversy.

5. Natural theology.

6. Moral theology.

7. The history of the church under the Old and New Testaments.

The practical sciences are,

1. Homiletic theology.

2. Cathetic theology.

3. Casuistic theology.

We do not here particularly name the *patristic theology*, (*theologia patrum seu patristica*), because all Christian communions are not agreed in their opinions concerning the degree of authenticity and infallibility that is to be attributed to these ancient fathers of the church. The Protestants believe, that these primitive theologians were liable to error in their sentiments as well as those of our days; and, in all probability, that they were less skillful, less learned, less clear, and less accustomed to close reasoning, than the latter, as philosophy was then more imperfect. But as we find in the writings of these fathers, many elucidations of the doctrine of the primitive apostles, and many irrefragable testimonies of the authenticity of divers remarkable events, which serve to establish the truth of Christianity; and as we there see, moreover, the origin of errors, of arbitrary ceremonies, and of many doctrines that have been introduced into the Christian church; the reading and the study of these fathers cannot but be of great utility to the theologian. To a virtuous citizen, who unites such various sciences, and employs them in pointing out to his fellow-citizens

the path that leads to temporal and eternal felicity; in a word, to a wise theologian, what veneration is not due?

SECT. I. Of the DOGMATIC.

UNDER the general term of dogmatic, we comprehend that part which the different writers on theology have called sometimes *theoretic*, sometimes *systematic*, and sometimes *thetic theology*, &c. The term *dogmatic* appears to us the most general, and the most just, to express the subject that we intend, as it comprehends an entire system of all the dogmas or tenets that each religion professes: whether it teach these dogmas by the way of theses, as articles of faith; by public lecture; by catechising; or any other manner whatever.

Every positive religion must naturally have a system of certain points of doctrine to propose to its followers; otherwise each one would form a particular system according to his own fancy: there would be as many different religions as there are individuals on the earth, and each society would consist of a confused mass of fantastic opinions; as the different modes of thinking, and the different degrees of discernment, are varied and compounded by mankind to infinity; but truth, on the contrary, is uniform and invariable.

The Christian religion is as compound in its dogmas as it is simple in its moral principle. It includes, 1. The dogmas founded on the lights of reason. 2. Those drawn from the Old Testament and the law of Moses. 3. Those taken from the New Testament and the doctrine of JESUS CHRIST. 4. Those that the fathers of the church have drawn from the Holy Scriptures. 5. Those that the church under the New Testament has prescribed to Christians by oecumenical and other councils assembled in different ages. 6. The dogmas that the popes, in quality of heads of the church, have established by their bulls: and to these must be added, on the part of the Protestants, 7. The dogmas that the reformers, especially Luther and Calvin, have taught. 8. The decisions of synods; and lastly, the tenets that are maintained by the different sects, as Socinians, Anabaptists, Quakers, &c. Each of these particular religions or sects pretend to support their dogmas both by reason and revelation: we do not here offer a work of controversy, and are very far from attempting to determine on which side truth and reason are to be found.

Our zeal, however, for the Christian religion in general, which we regard as perfectly divine, and as the only religion adapted to promote the happiness of mankind in this world, and to secure it in the next, and the desire we have that it may endure to the end of time, compels us to make in this place one important reflection; which is, that simplicity is ever an essential attribute of perfection, as complexity is of imperfection. Now, it cannot be denied, without doing violence to truth, that among the different dogmas of which we have been speaking, there are several that seem to be founded on speculations very abstruse, on subtleties very intricate, and on interpretations very ambiguous. God certainly never intended that all mankind should be theologians; he has not given them his divine word to be the cause of discord among men, nor that they should pass their whole lives in a painful search after objects of belief and articles of faith;

faith; and that they should forego, in that pursuit, the necessary offices of life, and their duties as citizens. The dogmas, then, essentially necessary to the welfare of mankind, ought to consist of a small number, and to bear the marks of simplicity and perspicuity; without which they must be imperfect, and consequently the work of man. Our intention, in making this remark, is, to extend our voice, if it be possible, even to posterity, whom we would conjure not to injure our religion, so holy and so admirable, by a multiplicity of dogmas. It is necessary, however, that the divine, who makes it his study and his profession, should be thoroughly acquainted with the theory of this science, in order that he may be able to instruct the sincere Christian, and to explain the nature of each particular dogma, as well as the solidity of its proofs; and to this it is that the study of the dogmatic leads; of which we shall now continue the analysis.

The dogmatic is then nothing but a *fuccinct exposition of all the dogmas of the Christian religion, in a natural and philosophical order*. By the word philosophical, we do not here precisely mean the method of mathematicians, in the manner the late M. Wolff has applied it to philosophy; every subject is not capable of a demonstration so exact and rigid; but a regular order is required in the arrangement of the general system, and a connection is to be preserved in the several matters that form it: the definitions should be just; the divisions exact; the arguments solid; the proofs clear; the citations conclusive; the examples striking; and, in a word, every thing should be adduced that appertains to so important a discipline.

It is very essential, moreover, in the dogmatic, at the beginning of each thesis, to explain the several terms that are peculiar to it, and that use has established in treating of theology; to draw from each definition certain axioms, and from thence to form propositions, and to illustrate them by solid reasoning. Lastly, we should not neglect, in such a system, to make use of the expressions used in the symbolic books that have been received by the whole Christian church, and which cannot be rejected or altered, without causing a confusion in our ideas, and in the general system of the Christian religion. But before we make the least advance in the study of Christian theology, it is indispensably necessary to examine the proofs by which the truth, the authenticity, and the divinity of the sacred and canonical books are established; for this is the foundation of all the dogmas, and the axis on which its whole doctrine turns.

The systematic part of the Christian religion, among the great number of its dogmas or theses, has *three principal*, from which all the rest are derived, and which form the basis of its whole doctrine:

1. The existence of one God in three persons.
2. The necessity of a Mediator or Redeemer.
3. The real appearance of the Mediator or Messiah on the earth.

Whoever writes, professes, or teaches the dogmatic, should be, above all things, careful well to establish these important truths; to evince them by the strongest and most evident proofs, drawn partly from the lights of reason, and partly from revelation; and he will then see with what facility all other theses flow from, and how easy it will be to prove them by, these.

The infinite variety that is found among mankind in their manner of thinking, and in their method of treating subjects; the frequent changes that have happened in the exterior form of philosophy, and in the method of treating it; the oppositions that have been raised at all times against divers doctrines of the Christian religion; all these have produced among theologians, different systems of the dogmatic. Sometimes they have combined positive theology with morality, and have formed a system that they call *theologia theoretico-practica*, or *theologia thetico-moralis*, &c.: sometimes they have refuted the arguments that others oppose to certain theses; and from thence has arose a system that they call *theologia thetico*, or *dogmatico*, or *positivo-polemica*: sometimes they have joined to natural theology that of revelation; and have formed a dogmatic, called *philosophico-theologica*: and so of the rest. But, besides that these distinctions and denominations are in themselves pedantic, it is at all times more eligible, in every science, to avoid confounding with each other the several branches of which it consists. The different dogmas, morality, philosophy, and controversy, are separate articles; and when each of these parts of theology are separately treated, they are disposed with more order in the mind, and a greater light is diffused over their several subjects.

It appears, moreover, from the simple enumeration that we have made above, of the different principles on which the dogmas of the Christian religion are founded, that, to be thoroughly acquainted with its whole theory, the theologian should also apply himself to the study of the symbolic books of its communion, and especially should be well versed in the Creed of the Apostles; that of Nice and St. Athanasius; the book called *Formula Concordiæ*; the Theses of the council of Trent; the Catechisms of Luther; the Confession of Augsburg; the Articles of Smalcalden; the Catechism of Heidelberg, &c. That he should be well acquainted with that part of theology that is called *patristica*: that is to say, that he should be well read in the fathers of the church; that he should not be ignorant even of scholastic theology; that he should at least know the frivolous subtleties and the complicated method of the ancient scholastic divines, which was derived from the philosophy of Aristotle and the schools; that he should make a serious study of the sacred history of all ages, the councils and synods; that he should, above all, never lose sight of natural theology; and lastly, that it is indispensably necessary that he should procure a good bibliothèque, or treatise of ecclesiastical writers (A), which he may consult occasionally, and learn from thence to know the best guides. The more a theologian applies himself to all these subjects, the more ability he will acquire in this science, and the more perfect he will be in the theory of that religion which it is his duty to teach to others.

Revealed religion being founded (at least in great part) on natural religion, and philosophy being the source from whence the principles and the knowledge of the latter are derived, it is evident that philosophy is intimately connected with theology: nevertheless, the aid of the former is to be employed with precaution, and is not to be regarded as the foundation of the theological dogmas, but only as a mean by which they may be explained and enforced. The Holy Scrip-

ture

(A) Those of Du Pin and William Cave are most celebrated.

SECT. II.

T H E O L O G Y.

Hermeneu-
tic
Theology.

tures constitute perpetually the true basis of revealed theology : philosophy effectually concurs, however, to prove the existence and the attributes of the Supreme Being ; the necessity of the creation of the universe by Almighty God, in opposition to every other possible manner of its being produced : it furnishes, moreover, plausible conjectures concerning the intention of the Almighty in creating this world ; it proves the necessity of a perpetual power to preserve it ; it supposes, that as God could not produce any thing that was not perfect in its kind, he could not have created man as he now is ; it vindicates the conduct of the Supreme Being, in appointing chastisements for transgressions, by showing that moral evil was not introduced into the world by absolute necessity, but by the abuse of liberty, the most noble prerogative of the human soul ; it determines the necessity of a Mediator ; it furnishes arguments for the belief of the immortality of the soul, and of a future state that has a relation to the moral actions of this life ; and lastly, it inspires a love of God as a Being of sovereign perfection, a gratitude towards him as our Creator and Preserver, and a submission to his will as our Supreme Ruler and Director ; motives of all others the most powerfully conducive to a virtuous conduct.

It is this use which theology makes of philosophy, that has given occasion to divide the theses of the dogmatic into pure and mixed ; that is, into theses that are founded entirely upon revelation ; and such as arise from an union of reason with revelation. Of the first sort are, 1. The article of the Holy Scripture itself ; which treats of its divine origin, its authority, and its efficacy. 2. The dogma of the Trinity. 3. That of the origin of evil, or of original sin. 4. The whole article of Jesus Christ. 5. The dogma of the efficacy and operations of the Holy Ghost. 6. That of the sacraments. 7. That of repentance. 8. That of the belief in Jesus Christ. 9. That of good and bad angels. 10. That of the end of the world, and the last judgment. 11. That of the church, &c. The mixed dogmas or theses are, 1. The doctrine of a Supreme Being in general ; his beings, his attributes, and his works. 2. That of the creation. 3. That of providence, or the conservation of the world. 4. Of sin, as a transgression of the laws of God. 5. Of rewards and punishments after death, &c. He that attentively studies, thoroughly comprehends, and well digests, all these theses, will have reason to rest content with his knowledge of the dogmatic.

SECT. II. *Of the EXEGETIS and the HERMENEUTIC.*

The term *Exegetis* is derived from the Greek verb *EXEΓNASTAI*, which signifies to relate or explain ; and that of *Hermeneutic* from *ERMEŒUEIN*, which means to search into ; and, in a figurative sense, thoroughly to examine and interpret. The learned, but especially the theologians, make use of these words, sometimes as synonyma, to express the same thing, and sometimes (as there are scarce any terms that are perfectly synonymous) to denote a small difference between two parts of learning of the same nature. By the word *Exegetis* they mean, that science which teaches clearly to investigate the true sense of the original text of the Holy Scriptures ; and by the *Hermeneutic*, the art of interpreting and explaining the Holy Scriptures to others (a).

VOL. X.

(A) The *Exegetis* is a kind of rational grammar. The *Hermeneutic* is the art of interpreting entire passages.

This distinction is so subtle, that it becomes almost frivolous. They are, in fact, the same science ; the one is only an explication of the other, and for that reason we think we are authorized to treat of them together in this place.

In order to the true understanding of the sacred text of all the books contained in the Holy Bible, whether of the Old or New Testament, it is absolutely necessary that the theologian be thoroughly acquainted, not only with the languages in which these books were originally wrote, but likewise with the history and antiquities of those remote times in which their authors lived. With regard to researches into the history of the Jewish nation, their antiquities, their morals, and their customs, it will be found advantageous to pursue it as far as the nature of the subject will admit, without, however, engaging in critical subtleties that lead to a labyrinth to which there is no end, and have spread more clouds over theology than even the scholastic controversies have formerly done.

He who would successfully interpret any work whatever, should first consider the spirit in which it is wrote : he should attentively reflect on the general design of that work, and the particular motives that induced the author to undertake it ; his genius, his passions, his taste ; the time, the place, and the people for whom it was written. These considerations are, above all, necessary, when we would undertake the explication of the Holy Scriptures. Independent of those reflections which the theologian will of himself naturally make on the subject, the excellent commentaries which we have on the Bible, in which the greatest men of every age have exercised their genius, may serve him as a guide in this course. The critical histories will likewise afford great aid, and throw admirable lights on this matter. Clear ideas, an acute discernment, and a solid judgment, will complete the work.

Furnished with ideas from such sources, the theologian may venture to investigate the true sense of those passages of Holy Scripture that may appear to him obscure, contradictory, or difficult, and to interpret them to others : but he will be more wise and less vain than to attempt to impose his decisions on mankind, at all times, as authentic and infallible. The human discernment is ever confined and imperfect ; and God has not granted to any man, to any theologian, or assembly of divines, an exclusive power of interpreting his divine word : he has moreover denounced his anathema against all those who shall add or take away a single word thereof. But to explore the true sense of any passage, and to explain it to others, cannot certainly be deemed either adding or retrenching.

SECT. III. *Of MORAL THEOLOGY.*

If it were allowable to compare the Saviour of the world to a weak mortal, we would say, that the conduct of Jesus Christ resembled that of Socrates, who has left us no part of his doctrine in writing, but whose whole instructions (as well as the particulars of his life) have been collected, digested, and published, by his disciples. The evangelists are the only historians of the Messiah : it is to their labours that we owe the knowledge of his actions upon earth, and his divine doctrine. The four Evangelists, and the Acts of the Apostles wrote by St Luke, contain therefore

43 C

alone

Moral
Theology.

alone the history of the life of Jesus Christ, and the doctrine that he taught. His apostles and disciples began by paraphrasing his doctrine, as well by their evangelic sermons as in the epistles they addressed to the faithful of several Christian churches: they have given explanations, and have added pastoral instructions, which are in effect admirable; but which, nevertheless, form not the original text of the discourses of our Saviour. The bishops of the apostolic century, the fathers of the church in all succeeding centuries, the other bishops and ecclesiastics, the councils, the synods, the doctors of theology, the popes, the confessor, the reformers likewise, and an infinity of theologians, have drawn from the Gospel, and sometimes also from the letters of the apostles, and from other commentaries on the gospel, various tenets; which, united, form at this day the general system of the Christian religion. The theologians who devote themselves to the service of the altar, study this system in the dogmatic; the laity learn it by means of catechisms; and after they have made confession of their faith, solemnly adopt it when they are received into the bosom of the church.

It is not the same with regard to the morality of Jesus Christ, which every one may read in the Gospel; and to know which, it is not necessary to become learned, nor to study a complicated system. If the dogmatic were not armed with a thousand arguments to establish the divinity of Jesus Christ, yet would the morality of his gospel sufficiently prove it; seeing that it is perfectly holy, entirely simple, strictly just, and most completely adapted to promote the felicity of the human race in this world, and in that which is to come. The Saviour of the world has not enjoined any part of mankind to engage in disputes or abstract refinements: the sole command that he has given them is, *to believe in his gospel*; and that is comprised in one word only, *Love*: the grand and only principle on which the whole of his sacred doctrine is founded.

To produce the greatest effects possible by the least efforts, is the highest perfection in nature, and at the same time the true characteristic of divinity. God has given to all the beings that compose the universe, one simple principle alone, by which the whole, and every part, is connected and perpetually supported; and that is *Love*. The attraction of the celestial bodies, as well as of those of which our globe is formed, is a species of *love*; a mutual tendency toward each other. The uniform generation, by which all beings are perpetuated, is founded in *love*. This is the true *minimum*, the true system of *the least action*, which includes something so divine. It appears to be the will of God to establish by the mouth of the Messiah, the same simple principle in morality, that is, in the rule of human actions, by saying *Love*: in a word, it was his will, that in the conduct of mankind, as in every other part of nature, there should be no other principle than that of *Love*.

That in the different systems of ethics of the ancient heathen philosophers many maxims and precepts of admirable morality are to be found, cannot be denied; but, beside that these philosophers are almost continually contradicting each other in their maxims, no one of their systems is founded on the true principle.

Moral
Theology.

In searching after it, they have discovered some excellent truths; but it has been by chance, and they are at best imperfect. Jesus Christ has alone taught mankind perfect morals, by deducing them from this true principle. Every principle should be simple: the idea of a compound principle implies at once an imperfection. Every principle should be comprehensive, even universal, in its effects. Every principle, whose effects are limited, is imperfect. God himself is uniform in his principle, and infinite in his effects. His doctrine, or his law, should be the same. Jesus Christ has made known to mankind this principle, simple and universal. He has therefore been, in this sense also, the true Saviour of the world. He has preached to mankind; and his only doctrine has been that of *love*.

By the word *Love*, with regard to bodies in general, is meant a tendency, a mutual inclination, that urges them to join and to coalesce; and with regard to men in particular, a lively affecting pleasure that possesses the mind on contemplating the perfections of any object. This pleasure is always accompanied with a desire either to possess that object, or to render it propitious. By adopting therefore this principle, and this last definition of *Love*, it follows, that all the duties of man consist, 1. In the love of God in preference to all other objects. 2. In the love of himself. 3. In the love of his own species. 4. In the love of every other creature to a certain degree.

The doctrines of Jesus Christ are, in these respects, the most explicit.

From this principle flows our duty towards God, towards ourselves, our neighbour, and to those beings that are subject to our power. The first rule is, to communicate to all those, whom it is our duty to love, all the good, and to preserve them from all the evil in our power. The second, to do to no one what we would not have done to ourselves in similar circumstances. The third, which is the simple effect of love, is to endeavour to please the object that we ought to love. The fourth, to endeavour to render the pleasures that we communicate to others, as lively as possible, and those inevitable evils, which we are sometimes constrained to do to them, as supportable as we can; and so of the rest. The whole evangelic doctrine of our Saviour is replete, from beginning to end, with admirable precepts for these purposes; and these precepts, with their applications, general and particular, we learn from that science which we call *moral theology*.

This doctrine we distinguish from moral philosophy, or the simple doctrine of Ethics; because Jesus Christ has made known, in his divine morality, a far greater degree of perfection than is discoverable by the mere light of human reason. For the renouncing of self-interest, and private pleasure; the forgiveness of offences; the love of his enemies; the triumph over destructive passions; and many other like virtues, the Christian is alone indebted to the doctrine of Jesus Christ.

A second difference between Christianity and philosophy consists in this, That the first adds to the second still new motives to the practice of virtue. That of redemption and pardon, obtained by Jesus Christ, is not one of the least. Its argument is this: If God has so loved mankind, as to afford them the means

means by which the evil, caused by their own fault, may be abolished, it would be the greatest of all ingratitude and malice towards himself, if man should not endeavour to acknowledge this love, to merit it, and to embrace the means of pleasing God. A third motive, taken also from the merit of Jesus Christ, here offers itself as an auxiliary to the two former. According to the Christian doctrine, man has not by nature the power to practise all those virtues which are agreeable to God: but the same doctrine teaches, on the other hand, the conditions by which it is possible to please that most holy and perfect Being; and gives the Christian hope also that he shall never labour in vain.

Lastly, the Christian morality is of far greater efficacy in adversity than philosophy: it carries with it a wonderful consolation in misfortune, and even in the hour of death; for the Christian may say, with the Apostle, *that godliness (or the practice of evan- gelic morals) is in all things profitable, having the promise of the present life, and that which is to come.*

SECT. IV. Of POLEMIC THEOLOGY, or CONTRO- VERSY.

We cannot sufficiently lament, that the church of the God of peace should be a church-militant; and that a doctrine so simple and clear as that of the Gospel should be the cause of discord even among Christians themselves. Nevertheless, as the truth is so difficult to discover in all things, and especially in matters of religion; as it is so frequently covered with the clouds of interest and ambition; as the same object appears so different to different men; and as error in the face of the world constantly assumes the mask of truth; it is but just that the true religion be furnished with arms to combat error, and to pluck off that deceitful mask by which so many poor mortals are seduced.

The theologian, who has made the proper preparatory studies, who is thoroughly instructed in natural religion, in the dogmatic and the hermeneutic, and who joins to these sound logic, is already well prepared for this spiritual combat: he is armed, but he is still to learn how to use these arms: he must also be made acquainted with the enemies he is to encounter, to know their force, and the arts they will use against him. It is plain enough, we suppose, that we here speak of spiritual arms; of those with which we are furnished by reason and the Holy Scripture: evil be to him that employs any other: force is ever an infallible proof of the want of argument. The propagation of a religion by the sword, after the manner of Mahomet; persecutions, either secret or open; constraint, violence, every sort of religious war, is so atrocious, so contrary to the spirit of the Gospel, in a word, so detestable, that every true Christian must avert his sight from such infamous horrors.

Controversy is conducted either from the pulpit or chair, by way of harangue, by conversation, or by writing. The first quality that is necessary to a disputant is reason, and the next moderation; in what manner soever the contest is conducted, these two qualities should constantly be manifest, during the whole course of altercation.

There are some errors that attack the system of re-

ligion, and there are others that attack even its morality. In order properly to oppose an error, we must begin by finding out its real meaning: we must therefore study the different systems of other religions, and the principal heresies, if we would successfully refute them. We do not mean by this, that the theologian should know all the errors that spring up in the brain of each individual; we speak only of those that are professed by whole sects.

They who attack our religion, found their opinions either on the interpretation of the sacred text, or on philosophy or history; and we should always oppose them with the same arms with which they pretend to defeat us. It is necessary to begin by divesting ourselves of all prejudice, in order the better to show others those prejudices by which they are deluded. We should never make use, but especially when we oppose weak minds, of opprobrious terms in the course of the debate, nor contend about words or expressions, nor attack incidental circumstances that may attend erroneous principles; but bend our whole force against the root of the tree, the principal error; to uncover it, to dig it up, to destroy it.

Polemical theology is taught in universities by two methods, according to the views of the student. If he learn it merely in order hereafter to defend his parishioners against the most prevalent errors, he is only to examine the principal controversies according to the systematic order of theology; and may content himself with knowing their true meaning, together with the arguments of those that oppose them. But if it be his intention to teach this science to others, or to engage in controversy, either by conversation or writing; in short, if he aspire to renown in it, he should study the origin and history of each controversy, he should make himself a complete master of the arguments for and against it, the exceptions that it makes, its interests, its different revolutions and actual state, &c. These follow, in this study, either the order established in the dogmatic, or that which is used in symbolic books, that is, such as treat on articles of faith.

In order the better to elucidate the method to be observed in this sort of study, we shall say, that to acquire a complete knowledge of theological disputes, the student should, 1. Make the examen of each religion, and even of each controversy. 2. He should thoroughly examine his system in the symbolic books, and likewise the sources of his religion. 3. He should precisely determine the principal and capital error of each religion, sect, or individual; that which is the source from whence all the other errors flow. 4. Search into the political causes of each error, and each controversy, from history. 5. Examine the natural order according to which all the errors have taken their rise, the one from the other: and lastly, 6. Confront the respective arguments, the answers, and exceptions, that each party has made to defend its cause. To all this is to be added, 7. What they call *collegium disputatorium*; an exercise by which all that is learned in the closet and in the schools is called forth and animated, under the inspection of a professor; and the mind is accustomed to think, and the tongue to speak, with facility and efficacy.

The principal contests in which the theologian may be engaged, are, 1. Against those who admit of no revealed religion; as the atheists and deists. 2. Against those who admit of a revealed religion, but adopt not the true Revelation; as the Heathens, the Mahometans, &c. 3. Against those who believe only a part of the true Revelation; as the Jews. 4. Against those who add to the true Revelation matter foreign to it; as traditions, &c. 5. Against those who make a false interpretation of the sacred text, and draw from it erroneous systems; as the heretics and the schismatics, &c. And lastly, 6. Against those who make a wrong use of certain expressions of Revelation, and build on whimsical notions, ridiculous systems; the Fanatics, &c.

According to this division, the theologian will have to combat principally with,

1. The Atheists, with Spinosa at their head. 2. The Deists. 3. The Heathens and Idolaters. 4. The Mahometans. 5. The modern Jews. 6. The Arians and the Manicheans, or rather those who in these days follow their ancient errors. 7. The Socinians. 8. The Catholics, opposed to the Protestants. 9. The Protestants, opposed to the Catholics. 10. The Molinists, opposed to the Jansenists. 11. The Jansenists, opposed to the Molinists. 12. The Reformed, opposed to the Lutherans. 13. The Lutherans, opposed to the Reformed. 14. The Arminians. 15. The Anabaptists. 16. The Quakers. 17. The Fanatics, at the head of whom is Jacob Bohm. 18. The Pietists. 19. The Moravian Brethren, or the Herenuthers, &c.

Now, as each of the religions, communions, or heresies above-mentioned, have not scrupled to publish to the world their dogmas and creeds, the theologian ought carefully to instruct himself in those symbolic books, in which each of them have comprised its system; to study and to make a good analysis of them; and to prepare such arguments as are the most just, the most weighty, and proper to confute them.

Before we quit this subject, there is one remark to be made, or rather one caution that is very essential, which we would offer to the young theologian; which is, that the polemic is useful, and even necessary, in the study of theology in general; but that it is a discipline which ought to be treated with great prudence and moderation. Disputation in general is a dangerous art; and religious disputation is a deceitful art, and of infinite peril. The student will do right well to remember, that there is no sect, no communion on earth, that is perfectly true in all its dogmas without exception; that there are some small errors in all religions; that infallibility never was, nor ever will be, the portion of humanity. He should likewise remember, that the masters who teach him, or the books that he reads, are constantly partial to the religion they profess; and that when he has supported a thesis, and confuted his adversaries in a collegial dispute, (where his adversaries, as well as his preceptors, are of the same side of the question, and will not fail to adjudge him the victory), he should be persuaded, that the victory would not have been so easily obtained had he contended with able adversaries of the opposite religion: he should remember, that we triumph without glory when we combat without danger; and let him not be vain of his laurels, nor imagine himself some wonderful scholar; seeing that it

is very possible that he may go off victorious from such a dispute, that he may receive vast applause from his professors and his colleagues, and at the same time have reasoned like a dolt.

On the other hand, the most able theologians, and the most consummate professors in this science, ought to be constantly on their guard against the abuse of polemic theology; which frequently serves less to clear and confirm the truth of the dogmas of a communion, than to establish perpetual discord and hatred among Christians. Every theologian should also remember, that, by the nature of the subject, it is not possible to produce demonstration in support of his theses and opinions; but that his arguments will be only valid, and preponderate in proportion to their degree of evidence; and lastly, that it is a ridiculous and insufferable vanity to imagine, that every man, who does not think precisely as we do, is guilty of palpable error.

SECT. V. PASTORAL THEOLOGY.

HAVING described the theoretic sciences of theology, we now come to those which regard the practice. It would be to bury the talents that God has given him, and the studies that he has made, if the theologian did not employ them to the edification of his neighbour and the prosperity of the church. His office in society is attended with constant and anxious labours. He is charged with the cure of souls, with the instruction of youth, with preaching of the Gospel, the conduct of his flock, and the administration of the sacraments, with visitations to the sick and the dying, with calming the terrors of weak minds, with administering comforts to afflicted souls, and many other functions equally difficult and important.

As the homily makes a part of eloquence, it is unnecessary to say any thing of it in this place, but treat the others in their order.

It is in vain that a son of the church possesses all the sciences that belong to his profession, that he is an agreeable and even a renowned preacher, if he does not give a life, an efficacious spirit, to his ministry, by a good example; for that is the first precept in pastoral theology. He is at the head of a flock, and ought to be their guide: but how absurd, if his words and his actions be at continual variance with each other! How scandalous, if he be not the first to practise these lessons of wisdom that he preaches! How indecent, if while he edifies by his discourses, he disgraces by his morals! What baseness, if he should even glory in his irregularities! It is less shameful for a soldier to relate that he has tamely suffered an affront, than for an ecclesiastic to boast of his debaucheries! Both the one and the other is a disgrace to his profession.

But this exemplary conduct should be free from all affectation in the external behaviour. A singularity of dress, and an air of austerity; the head declined, the eyes turned up to heaven, the hands constantly clasped, a plaintive tone of voice, and a solemn gait; a scrupulosity in things indifferent, and a dogmatic and clerical manner of deciding in the common affairs of life; a ridiculous inclination to discover iniquity in innocent actions; to confound pleasure with vice, and to be an enemy to joy, the greatest boon that God has bestowed on man; and a hundred other like fopperies there are, with which the religious make a parade,

that

that is shocking both to good sense and the evangelical morality, and which render their ministry, in the eyes of sensible people, more contemptible than respectable. These are rocks on which the young theologian is much too liable to run, and of which he cannot be sufficiently cautioned.

After this candid caution and brief introduction, we pass to the examen of the different parts, the union of which composes the system of the pastoral, the most important article perhaps in all theology. The design of Revelation was, without doubt, to conduct man by faith to a virtuous life. It is not the opinions or the learning of weak mortals that can determine their intrinsic merit; it is their wisdom, their regularity of conduct, that must stamp their value. Experience shows, that a man of great genius and learning may be also a great villain; one who is unable to please God or his neighbour: the virtuous Christian, on the contrary, must be agreeable to both: it follows therefore, that the practical part of theology, which leads mankind to a virtuous conduct, is of all its parts the most important.

SECT. VI. CATECHETIC THEOLOGY.

By Catechetical Theology is meant, *The art of teaching youth, and ignorant persons, the principal points of the Evangelical Doctrine, as well with regard to belief as practice.* This application of the theoretic sciences of the theology ought to be conducted in the most simple manner possible. It is not every one who is possessed of the talent of properly composing and delivering catechetical instructions: and it is an art that is very necessary in the Christian church.

The greatest difficulty consists in separating the articles of faith that are absolutely essential and indispensable to the salvation of mankind, from those that are subtle and speculative, more liable to contradiction, and less necessary to such as do not make theology their profession. However, as children do not always remain children, and as the church is composed of persons of both sexes and of all ages, it is necessary that, in the explanations of the catechism, there should be employed different degrees of simplicity, proportioned to the age and capacity of those that are to be instructed. It is expedient for young people to retain in their minds the first principles of religion, such as are contained in good catechisms; and that they be explained to them in particular lectures; which is the most usual and most natural method of enabling youth to give an account of their faith. The sermons that are given in the Catholic churches on controversy, and in Protestant churches on the catechism, serve to instruct those who are of riper years and have their judgment more formed. These sermons compose, at the same time, a sort of course of the dogmatic and the polemic theology.

Both in private catechising, and in sermons that are purposely intended to explain the catechism, the theologian should avoid, as much as possible, the use of technical terms; or (which is still better) he ought to begin by explaining those terms, of which he should give such clear and determinate definitions, that no person of a moderate capacity can possibly mistake them. In a word, he should endeavour more to prove than to persuade; and as eloquence sometimes persuades at the

expense of truth, he should cautiously avoid that sort of delusive persuasion, and in its room substitute clear and solid argument.

SECT. VII. OF CASUISTIC THEOLOGY.

By casuistic theology is meant, the science that decides in doubtful cases of moral theology, and that calms the scruples of conscience which arise in the Christian's soul during his sojourn in this world.

The studies relative to these objects, which the theologian is supposed to have made, and the confidence that the common rank of Christians place in their pastors, afford them the means and the opportunities of rendering signal service to those of their fellow-citizens who have need of their counsel and consolation: for where there is one man of a philosophic spirit, one Christian of a well-grounded knowledge in theology, there are in a society a thousand that are not, and who are yet desirous of being instructed, guided, comforted, established. It is therefore both just and important that he who devotes himself to the service of the altar, should early study all those sciences that will enable him worthily to perform this important part of his ministry.

God forbid, however, that we should countenance the abuse that is made, in some Christian countries, of the duties that we have here explained. To reduce these matters into a political system; to make the direction of consciences a profession, a regular trade; to provide each house with a spiritual director, as with a butcher or baker, a steward or porter, who by that means may insinuate himself into the confidence of families, and become the depository of all their secrets; may sometimes sow discord between husband and wife, or the nearest relations; who may avail himself of the confidence of his devotees, to direct them constantly in matters of a worldly, and sometimes even of a criminal nature; to efface the legitimate and sacred authority of the father of a family, and in its place to substitute a foreign power; to undermine the confidence, the union and concord of families, in order to confirm and render necessary this secondary authority; to captivate the spirit, and oft-times the heart, of a wife or daughter, and in general of weak minds; to enjoin them ridiculous mummeries that lead to fanaticism, and a thousand dangerous superstitions, or to religious exercises that divert them from their domestic duties; in a word, to assume an absolute authority over the consciences of mankind, is a pernicious invention, contrary to the evangelic moral, to the welfare of society, to the interest of the state, and to the sovereign authority; and well deserves an exemplary punishment.

But the cure of souls, faithfully intended, and properly limited, differs totally from this despotic power. He who is charged with it by a lawful vocation, should remember that there are four classes of men with whom he will be engaged: 1. With those of weak minds; of little knowledge and little ability. 2. With those whose spirits are afflicted by some great reverse of fortune. 3. With those of nice and timorous consciences, who suffer by their scruples, whether they be vain or rational. 4. And lastly, the wicked, the hardened and incorrigible sinner. The grand art here consists in representing to each of these classes of men, the truth, in a manner so clear, so strong and full, that they

they can no longer retain any doubts that conviction must take place, and consolation or conversion be the consequence.

Truth is in its nature highly problematic: each one, however, is persuaded that he knows it, that he possesses it, and is guided by it; every man thinks himself in the right. We should therefore begin by discovering the truth in the subject before us, and in placing it upon a solid foundation. This business of demonstrating the truth to others, is attended in the mean time with infinite difficulty. Every mind is not capable of discovering it at the first glance; nor can all discern it from the same point of view. Sometimes men require conviction by abstract or philosophical arguments, and sometimes by the express decisions of the Holy Scripture. Sometimes by authority, sometimes by gentle remonstrance, and sometimes by dreadful menaces. Sometimes they are to be reclaimed by properly exposing the necessary and fatal consequences that result from their conduct; and at others, by the alluring promises of the gospel. Now vice is to be boldly confronted; and now the transgressor is to be conducted into the right path by artful turnings: now the sinner's crimes are to be painted in the strongest colours; and now a veil is to be lightly cast over them; and sometimes we should even indulge a favourite inclination, in order to induce them to abandon a more pernicious passion: and so of the rest.

As it is impossible that the books which have been wrote on this subject, though of an immense quantity, can contain every case that daily occurs in the ministry of the gospel; and as these cases are not always justly decided by these authors; and, if they were, the consulting of such enormous works would take up too much of a theologian's time, and divert him from his other studies; and as these casuistic writers contain, moreover, a number of puerile subtleties and wretched chi-

meras; it is highly proper that the minister of the altar, whom we suppose to have a masterly knowledge of the principles, the dogmas, and moral of the Christian religion, should endeavour to draw from the true source the means that he is to employ on each occurrence, and not have recourse to books for their decisions. For which purpose it is necessary, 1. That he accustom himself to reason according to the rules of sound logic. 2. That he learn to know the human heart, under its different disguises; the characters of men, their arts, and ruling passions. 3. That he do not attempt to gain or convince by little pious frauds, or by lucky sophisms artfully represented. 4. That he do not inflict what are called *penances*, which are the height of absurdity. 5. That he do not enjoin mummeries, pilgrimages, austerities, and a thousand like matters, which can never carry with them a real conviction, and only serve to divert men from their labours and the duties of society. But, 6. That he constantly present, as we have before said, and cannot too often repeat, the truth, in all its native force and purity.

This truth, however, is no enemy to sacred eloquence; on the contrary, the latter serves to introduce the former into the mind of the auditor, and there to give it such strong impressions, as neither time, the dissipations of the world, nor the distractions of fortune, are able easily to efface. The whole ministerial function consists in teaching, preaching, administering the sacraments of the church, visiting the sick and the dying, comforting the afflicted, and affording the spiritual aids to all those who have need of them. Eloquence is of the greatest efficacy in all these functions; and, without affecting it, the minister of the gospel should never neglect it. There are some professors in universities who give their auditors a complete systematic course on pastoral theology, which may be attended with many advantages.

T H E

Theophilus
Theophrastus.

THEOPHILUS, the sixth bishop of Antioch; was raised to that see in 169, and instructed his church till about the year 182. There are still extant his three books, written in Greek, against the calumniators of the Christian religion, addressed to Autolyens. They were printed at Oxford in 1684, in duodecimo, under the inspection of Dr Fell. There are also other works attributed to him; but these are written by later authors.

THEOPHRASTUS, a celebrated Greek philosopher, was the son of Melanctus, and was born at Erebus in Bœotia. He was at first the disciple of Lucippus, then of Plato, and at last of Aristotle. He succeeded the latter in the 322 year before the Christian æra, and taught philosophy at Athens with extraordinary applause. He said of an orator without judgment, "that he was a horse without a bridle." He was accustomed to say, "There is nothing so valuable as time, and those who lose it are the most inexcusable of all prodigals." He died at above 100 years of age. Theophrastus wrote many works; of which the following are the principal of those that are still extant, 1. An excellent moral treatise intitled *Characters*, which he says in his preface he composed at 99 years of age. Isaac Casaubon has written learned Commentaries on this small treatise: it has been translated from the Greek into French, by M. de la Bruyere; it has also

T H E

been translated into English. 2. A curious treatise on Plants. 3. A history of Stones; of which Dr Hill has given a good edition, with an English translation, and learned notes, in 8vo.

THEOPHYLACT, archbishop of Achrida, the metropolis of Bulgaria, and one of the most learned men of the 11th century, was born at Constantinople, where he was instructed in ecclesiastical learning. He laboured with great zeal to establish the Christian religion in Achrida, where there were still many pagans, and died after the year 1071. He wrote Commentaries upon the Gospels, the Acts of the Apostles, St Paul's Epistles, and upon Habakkuk, Jonah, Nahum, and Hosea, and also several Epistles, and other works in Greek.

THEOFOMPUS, a celebrated Greek orator and historian, was born in the island of Chios, and flourished in the reign of Alexander the Great. He was one of the most famous of all the disciples of Isocrates, and won the prize from all the panegyristes whom Artemisa invited to praise Mausolus. He wrote several works, which are lost.

THEOREM, a speculative proposition, demonstrating the properties of any subject.

THEORETIC, something relating to theory, or that terminates in speculation. See **THEORY**.

THEORY,

Theophylact
||
Theoretic.

THEORY, in general, denotes any doctrine which terminates in speculation alone, without considering the practical uses or application thereof.

THERAPEUTÆ, a term applied to those that are wholly in the service of religion. This general term has been applied to particular sects of men, concerning whom there have been great disputes among the learned.

THERAPEUTICS, that part of medicine which acquaints us with the rules that are to be observed, and the medicines to be employed in the cure of diseases.

THERAPHIM, certain images or superstitious figures mentioned in Scripture. Some Jewish writers tell us, that the theraphim were effigies of human heads, placed in niches, and consulted as oracles. Others say, they were talismans, or figures of metal cast and engraved under certain aspects of the planets; to which they ascribe extraordinary effects.

THERIACA ANDROMACHI, a compound medicine made in the form of an electuary. See **PHARMACY**, n° 903, b.

THERMÆ, hot baths or bagnios. Luxury and extravagance were in nothing carried to such heights as in the thermæ of the Roman emperors. Ammian complains, that they were built to such an extent as to equal whole provinces; from which Valesius would abate, by reading *piscinæ* instead of *provinciae*. And yet after all, the remains of some still standing are sufficient testimonials for Ammian's censure; and the accounts transmitted of their ornaments and furniture, such as being laid with precious stones, (Seneca); set round with seats of solid silver, (Pliny); with pipes and cisterns of the same metal, (Statius); add to, rather than take from, the censure. The most remarkable bagnios were those of Dioclesian and Caracalla at Rome, great part of which remains at this day; the lofty arches, stately pillars, variety of foreign inarble, curious vaulting of the roofs, great number of spacious apartments, all attract the curiosity of the traveller. They had also their summer and winter baths.

THERMOMETER, an instrument for measuring the increase and decrease of the heat and cold of the air, by means of the elastic and expansive power of fluids.

The thermometer is an instrument of modern invention, but authors are not agreed on the person who was the first inventor. Sanctiorius affirms, that he himself had this honour; and his assertion is corroborated by the testimonials of Borelli and Malpighi. Boerhaave, however, ascribes it to Cornelius Drebbel; Muschenbroek to the Venetian Paul Sarpi; and Viviani to Galileo. It is not well known what was the form of the first instruments of this kind, only it is certain that they were far from being as perfect as they are at present. They were very clumsy; and air being the fluid employed, they acted also as a kind of *barometers*, and thus were entirely unfit for comparing the degrees of heat at the distance of any considerable time. The first improvement in their construction was made by Ferdinand II. great duke of Tuscany, or the members of the academy del Cimento under his protection. Spirit of wine inclosed in glass tubes hermetically sealed, was now employed; by which means evaporation was prevented, and likewise the pressure of the external air kept off. Instruments of this kind

were introduced into England by Mr Boyle, and very soon came to be universally used among the virtuosi in different parts of the world. However, they still laboured under great disadvantages; for as they were not adjusted to any common scale, tho' they would each of them show the comparative degrees of heat and cold in the bodies to which they were applied; yet they could never be compared with one another, nor could the observations made in different parts of the world be collected in such a manner as to answer any good purpose.

Mr Boyle was the first who proposed one certain and determinate degree of cold as a standard to be universally chosen from whence to begin the scale of thermometers, and which being at all times invariable, would keep the observations made by different thermometers sufficiently exact. The point he proposed was that in which the oil of aniseeds congeals; and he also mentioned that in which distilled water begins to freeze, as another which might be employed. At last, however, Mr Boyle laid aside both these standards; as thinking that the oil of aniseeds, water, and other liquors, might freeze in different degrees of heat. In this opinion he was followed by Dr Halley, who proposed for a standard the temperature of deep caves below ground. These indeed do always preserve the same temperature, but the use of them would be found not a little inconvenient for the purpose of adjusting thermometers; nor, after all, could there be any certainty even in this method; for we are by no means sure that the temperature of the ground is the same in all places at the same depth from the surface. Dr Halley therefore proposed another point, namely, that in which spirit of wine boils; and he also mentioned the heat of boiling water as a point very fixed and determined, and in which he has been followed by all that came after him.

From this one point of the heat of boiling water, it has been proposed to construct thermometers in such a manner that they shall all correspond with each other. This method is by marking the degree of expansion or contraction of the fluid in thermometers, as the heat applied is either greater or less than that of boiling water. Supposing, for example, the whole volume of this fluid to consist of 10,000 parts, we must mark on the tube, where that volume is expanded by heat or contracted by cold, 1, 2, 3, 4, &c. of these parts; all which may be done by different persons and in different places, so that they shall answer precisely to one another.—Yet this method, so plausible in appearance, is found not to be very practicable; it being difficult to determine exactly all the divisions from the alteration of the bulk of the fluid. The best method, therefore, is to have two fixed points of heat at a considerable distance the one from the other; such as that of boiling and freezing water; after which we are to divide the scale or tube between them into any convenient number of equal parts or degrees.

The method just now proposed is that which has for a long time been universally followed; and the only difficulties which remained in the construction of thermometers were the choice of a proper fluid, the adjusting of the two fixed points, and the division of the space between them in such a manner as to make proper allowance for any inequalities that might happen

to be in the diameter of the tube through which the fluid moves.

* See Cold, Congelation, and Quick-silver.

With regard to the fluid, quicksilver has universally obtained the preference, as being sooner heated and cooled than any other with which we are acquainted, and requiring so great a degree of cold to congeal it, that till very lately it was thought impossible to do so; though the contrary is now shown by undeniable experiments*. The heat also which quicksilver requires to make it boil, is very considerable, so that the scale on a quicksilver thermometer may be enlarged greatly beyond that made with any other fluid. In extreme degrees of cold, indeed, where quicksilver freezes, the thermometer should be filled with highly rectified spirit of wine, or the fluid petroleum, called *naphtha*; both of which are found unalterable in the greatest degrees of cold, either natural or artificial, hitherto observed in any part of the world.

The adjustment of the two fixed points of heat, viz. that of boiling and that of freezing water, has been found a matter of considerable difficulty, as they vary considerably according to the height of the mercury in the barometer at the time. Hence the greatest philosophers have not thought it below them to bestow their labour in attempting to bring this matter to its utmost exactness; and for this purpose a committee of the Royal Society was lately appointed.

This inaccuracy in the heat of boiling water at different times, was observed by Mr Fahrenheit, a celebrated artist at Amsterdam, from whom the kind of thermometers now mostly used took their name. He supposed the variation to be much greater than it really is; but Mr de Luc, by a great number of experiments made at different heights above the level of the sea, found a rule by which the difference in the boiling point, answering to different heights in the barometer, is determined with great exactness. According to this rule, the alteration of the boiling point by the variation of the barometer from $29\frac{1}{2}$ to $30\frac{1}{2}$ inches is $1^{\circ}.59$ of Fahrenheit. The committee of the Society (of whom M. de Luc was one), after a number of experiments which our limits will not allow us to insert, lay down the following practical rules for adjusting the boiling and freezing points.

“*Rules to be observed in adjusting the boiling point.*—The most accurate way of adjusting the boiling point is, not to dip the thermometer into the water, but to expose it only to the steam, in a vessel closed up in the manner represented in fig. 4. where *ABba* is the vessel containing the boiling water, *Dd* the cover, *E* a chimney made in the cover intended to carry off the steam, and *Mm* the thermometer passed thro’ a hole in the cover. Those who would make use of this method, must take care to attend to the following particulars.

“1st, The boiling point must be adjusted when the barometer is at 29.8 inches; unless the operator is willing to correct the observed point in the manner directed below.

“2^{dly}, The ball of the thermometer must be placed at such a depth within the pot, that the boiling point

shall rise very little above the cover; for otherwise part of the quicksilver in the tube will not be heated, and therefore the thermometer will not rise to its proper height. The surface of the water in the pot also should be at least one or two inches below the bottom of the ball; as otherwise the water, when boiling fast, might be apt to touch the ball: but it does not signify how much lower than that the surface of the water may be.

“3^{dly}, Care must be taken to stop up the hole in the cover through which the tube is inserted, and to make the cover fit pretty close, so that no air shall enter into the pot that way, and that not much steam may escape. A piece of thin flat tin plate must also be laid on the mouth of the chimney, so as to leave no more passage than what is sufficient to carry off the steam. The size of this plate should be not much more than sufficient to cover the chimney, that its weight may not be too great; and the mouth of the chimney should be made flat, that the plate may cover it more completely. It must be observed, that when the tin-plate is laid on the mouth of the chimney, it will commonly be lifted up by the force of the steam, and will rattle till it has slipped aside sufficiently to let the steam escape without lifting it up. In this case it is not necessary to put the plate back again, unless by accident it has slipped aside more than usual. If the artist pleases, he may tie each corner of this plate by a string to prongs fixed to the chimney, and standing on a level with the plate, as thereby it will necessarily be kept always in its place (*A*); but we would by no means recommend having it made with a hinge, as that might be apt to make it stick, in which case the included vapour might be so much compressed as to cause an error. We would also by no means advise lining the tin-plate with leather, or any other soft substance for the sake of making it shut closer, as that also might be apt to make it stick. The chimney also ought not to be made less than half a square inch in area: for though a smaller chimney would be sufficient to carry off the steam, unless the vessel is much larger than what we used; yet the adhesion which is apt to take place between it and the tin-plate when wet, might perhaps bear too great a proportion to the power which the included steam has to lift it off, if it was made much less. It is convenient that the chimney be not less than two or three inches long, as thereby the observer will be less incommoded by the steam; but it would be improper to make it much longer, for the longer the chimney is, the greater disposition has the air to enter into the pot between it and the cover.

“It is most convenient not to make the cover fit on tight, but to take on and off easily; and to wrap some spun cotton round that part of the cover which enters into the pot, in order to make it shut closer; or, what seems to answer rather better, a ring of woollen cloth may be placed under the cover, so as to lie between the top of the pot and it. These methods of making the cover shut close can be used more conveniently when the cover is made to enter within the pot, as in the figure, than when it goes on to the outside.

Plate

XLXVIII.

(A) Fig. 2. n^o 3. is a perspective view of the chimney and tin plate; *ABCD* is the plate; *E* the chimney; *Ff*, *Gg*, *Mm*, and *Nn*, the prongs fastened to the chimney, to which the four corners of the plate are to be tied by the strings *Af*, *Bg*, *Cm*, and *Dn*; the ends *F*, *G*, *M*, and *N*, of the prongs must be on a level with the plate, and the strings should not be stretched tight.

"There are various easy ways by which the hole in the cover, through which the tube of the thermometer is passed, may be stopped up, and by which the thermometer may be suspended at the proper height. The hole in the cover may be stopped up by a cork, which must first have a hole bored through it big enough to receive the tube, and be then cut into two, parallel to the length of the hole. Another method more convenient in use, but not so easily made, is represented in fig. 6, which exhibits a perspective view of the apparatus; *Aa*, is the cover; *H*, the hole through which the thermometer is passed; *Bb*, a flat piece of brass fixed upon the cover; and *DdEe*, a sliding piece of brass, made so as either to cover the hole *H*, or to leave it uncovered, as in the figure, and to be tightened in either position by the screw *S* sliding in the slit *Mm*; a semi-circular notch being made in the edge *Bb*, and also in the edge *Dd*, to inclose the tube of the thermometer: pieces of woollen cloth should also be fastened to the edges *Bb* and *Dd*, and also to the bottom of the sliding-piece *DdEe*, unless that piece and the cover are made sufficiently flat, to prevent the escape of the steam. In order to keep the thermometer suspended at the proper height, a clip may be used like that represented in fig. 6, which, by the screw *S*, must be made to embrace the tube tightly, and may rest on the cover. That part of the clip which is intended to bear against the tube had best be lined with woollen cloth, which will make it stick tighter to the tube, and with less danger of breaking it. Another method, which is rather more convenient, when the top of the tube of the thermometer is bent into a right angle, in the manner frequently practised at present for the sake of more conveniently fixing it to the scale, is represented in the same figure; *GgFf*, is a plate of brass, standing perpendicularly on the cover; and *L/Nn*, a piece of brass, bent at bottom into the form of a loop, with a notch in it, so as to receive the tube of the thermometer, and to suffer the bent part to rest on the bottom of the loop; this piece must slide in a slit *Kk*, cut in the plate *L/Nn*, and be tightened at any height by the screw *T*.

"4thly, It is best making the water boil pretty briskly, as otherwise the thermometer is apt to be a great while before it acquires its full heat, especially if the vessel is very deep. The observer, too, should wait at least one or two minutes after the thermometer appears to be stationary, before he concludes that it has acquired its full height.

"5thly, Though, as was said before, this appears to be the most accurate way of adjusting the boiling-point; yet, if the operator was to suffer the air to have any access to the inside of the vessel, he would be liable to a very great error: for this reason, we strongly recommend it to all those who use this method, not to deviate at all from the rules laid down, without assuring themselves, by repeated trials with a pretty sensible thermometer, that such alteration may be used with safety. But the covering the chimney with the tin-plate ought by no means to be omitted; for though, if the cover of the pot fits close, it seldom signifies whether the plate is laid on or not, yet, if by accident the cover was not to fit close, the omitting the tin-plate would make a very great error. Making the

chimney very narrow would not answer the end properly; for if it was made so small as to make the vessel sufficiently close when the water boiled gently, it would not leave sufficient passage for the escape of the steam when the water boiled fast.

"Another way of adjusting the boiling point is, to try it in a vessel of the same kind as the former, only with the water rising a little way, namely from one to three or four inches above the ball, taking care that the boiling point shall rise very little above the cover, as in the former method. In this method there is no need to cover the chimney with the tin-plate; and there is less need to make the cover fit close, only it must be observed, that the closer the cover fits, the less the operator will be incommoded by the steam. The height of the barometer at which the boiling point should be adjusted, when this method is used, is 29½ inches, or three-tenths of an inch less than when the former method is used.

"It will be convenient to have two or three pots of different depths; for if a short thermometer is to be adjusted in the same pot which is used for a long one, it will require a great depth of water, which, besides taking up more time before it boils, makes the observation rather less accurate, as the heat seems to be less regular when the depth of water in the pot is very great, than when it is less.

"Perhaps some persons, for the sake of heating the water more expeditiously, may be inclined to use an apparatus of such kind that the fire shall be applied to a considerable part of the sides of the pot as well as to the bottom; we would, however, caution them against any thing of that kind, as the observations are considerably less regular than when little more than the bottom of the pot is heated. If the pot is heated over a chafing-dish or common fire, we apprehend that there can seldom be any danger of too much of the sides being heated; but if the operator should be apprehensive that there is, it is easily prevented by fastening an iron ring an inch or two broad round the pot near the bottom. This precaution is equally necessary when the thermometer is adjusted in steam, especially when there is not much water in the pot.

"The greatest inconvenience of this method of adjusting the boiling point is the trouble of keeping a proper depth of water in the pot; as to do this it is necessary first to find the height of the boiling point coarsely by trying it in an open vessel, and then to put such a quantity of water into the pot that it shall rise from one to three or four inches above the ball, when the thermometer is placed at such a depth within the pot that the boiling point shall rise very little above the cover. The operator must be very careful that the quantity of water in the pot be not so small as not entirely to cover the ball.

"A third way of adjusting the boiling point is to wrap several folds of linen rags or flannel round the tube of the thermometer, and to try it in an open vessel, taking care to pour boiling water on the rags, in order to keep the quicksilver in the tube as nearly of the heat of boiling water as possible. The best way is to pour boiling water on the rags three or four times, waiting a few seconds between each time, and to wait some seconds after the last time of pouring on water before the boiling point is marked, in order that

meter.

the water may recover its full strength of boiling, which is in good measure checked by pouring on the boiling water.

" In this method the boiling point should be adjusted when the barometer is at 29.8 inches, that is, the same as when the first method is used; the water should boil fast, and the thermometer should be held upright, with its ball two or three inches under water, and in that part of the vessel where the current of water ascends (b).

" Whichever of these methods of adjusting the boiling point is used, it is not necessary to wait till the barometer is at the proper height, provided the operator will take care to correct the observed height according to the following table.

| Height of the barometer when the boiling point is adjusted according to, | | Correction in 1000ths of the interval between 32° and 212°. | Height of the barometer when the boiling point is adjusted according to, | | Correction in 1000ths of the interval between 32° and 212°. |

" To make use of this table, seek the height which the barometer is found to stand at in the left-hand column, if the boiling point is adjusted either in the first or third method, and in the second column if it is adjusted in the second method; the corresponding number in the third column shows how much the point of 212° must be placed above or below the observed point, expressed in thousandth parts of the interval between the boiling and freezing point: for example, suppose the boiling point is adjusted in steam when the barometer is at 29 inches, and that the interval between the boiling and freezing points is 11 inches; the nearest number to 29 in the left-hand column is 29.03, and the corresponding number in the table is 7 higher, and therefore the mark of 212° must be placed higher than the observed point by $\frac{7 \times 11}{1000}$, or .077 of an inch.

" This method of correcting the boiling point is not strictly just, unless the tube is of an equal bore in all its parts; but the tube is very seldom so much unequal as to cause any sensible error, where the whole correction is so small. The trouble of making the correction will be abridged by making a diagonal scale, such as is represented in fig. 4.

" It is not very material what kind of water is used for adjusting the boiling point, so that it is not at all salt; only, if any kind of hard water is used, it is better that it should be kept boiling for at least ten

minutes before it is used. But we would advise all those desirous of adjusting thermometers in the most accurate manner for nice experiments, to employ rain or distilled water, and to perform the operation in the first-mentioned manner, that is, in steam.

" On the freezing point.—In adjusting the freezing as well as the boiling point, the quicksilver in the tube ought to be kept of the same heat as that in the ball. In the generality of thermometers, indeed, the distance of the freezing point from the ball is so small, that the greatest error which can arise from neglecting this precaution is not very considerable, unless the weather is warmer than usual; but as the freezing point is frequently placed at a considerable distance from the ball, the operator should always be careful either to pile the pounded ice to such a height above the ball, that the error which can arise from the quicksilver in the remaining part of the tube not being heated equally with that in the ball, shall be very small; or he must correct the observed point, upon that account, according to the following table;

| Heat of the air. | Correction. |
|------------------|-------------|
| 42° | .00087 |
| 52 | .00174 |
| 62 | .00261 |
| 72 | .00348 |
| 82 | .00435 |

" The first column of this table is the heat of the air, and the second is the correction expressed in 1000th parts of the distance between the freezing point and the surface of the ice: for example, if the freezing point stands seven inches above the surface of the ice, and the heat of the room is 62, the point of 32° should be placed $7 \times .00261$, or .018 of an inch lower than the observed point. This correction also would be made more easy by the help of a diagonal scale, similar to that proposed for the boiling point.

" On the precautions necessary to be observed in making observations with thermometers.—In trying the heat of liquors care should be taken that the quicksilver in the tube of the thermometer be heated to the same degree as that in the ball; or, if this cannot be done conveniently, the observed heat should be corrected on that account."

After having adjusted the fixed points of thermometers in this manner, the division of the scale is easy; for by making a certain quantity of mercury, suppose as much as fills the tube the length of half an inch, pass through the whole length of it when open at both ends, we can perceive what length of space it occupies in different parts of the tube, and divide accordingly. However, even after thermometers are constructed in this manner with the utmost accuracy, a very considerable inconvenience attends the using them, namely, that the observer's eye must be on the instrument the very instant that the mercury stands at the highest or lowest degree; for since the time when that may happen is utterly uncertain, if it be not immediately noticed, it can never afterwards be known. The sultry heat of the summer's day, and the freezing cold of the winter's night, render it very

U.R.

" (n) In a vessel of boiling water one may almost always perceive the current of water to ascend on one side of the vessel, and to descend on the other.

meter.

unpleasant to be abroad at such times in the open air, although it is absolutely necessary that the thermometer should be so. It would therefore be a very great improvement could a thermometer be constructed in such a manner as to show the greatest height to which it had ascended, or the lowest point to which it descended, in the observer's absence. One of this kind has been constructed by Mr James Six, of which the following account is given by him in the 72d vol. of the Phil. Transf.

Plate
CC.LXXXV.

"Fig. 1. *ab* is a tube of thin glass, about 16 inches long, and five sixteenths of an inch in diameter; *cde fgh*, a smaller tube with the inner diameter, about one fortieth, joined to the larger at the upper end *b*, and bent down, first on the left side, and then, after descending two inches below *ab*, upwards again on the right, in the several directions *cde, fgh*, parallel to and one inch distant from it. On the end of the same tube at *b*, the inner diameter is enlarged to half an inch from *b* to *i*, which is two inches in length. This glass is filled with highly rectified spirits of wine to within half an inch of the end *i*, excepting that part of the small tube from *d* to *g*, which is filled with mercury. From a view of the instrument in this state, it will readily be conceived, that when the spirit in the large tube, which is the bulb of the thermometer, is expanded by heat, the mercury in the small tube on the left side will be pressed down, and consequently cause that on the right side to rise; on the contrary, when the spirit is condensed by cold, the reverse will happen, the mercury on the left side will rise as that on the right side descends. The scale, therefore, which is Fahrenheit's, beginning with *o* at the top of the left side, has the degrees numbered downwards, while that at the right side, beginning with *o* at the bottom, ascends. The divisions are ascertained by placing this thermometer with a good standard mercurial one in water gradually heating or cooling, and marking the divisions of the new scale at every 5° (c). Thus far our thermometer resembles in some respects those of Mr Bernoulli and Lord Charles Cavendish: but the method of showing how high the mercury had risen in the observer's absence, the essential property of an instrument of this kind, is wholly different from theirs, and effected in the following manner. Within the small tube of the thermometer, above the surface of the mercury on either side, immersed in the spirit of wine, is placed a small index, so fitted as to pass up and down as occasion may require: that surface of the mercury which rises carries up the index with it, which index does not return with the mercury when it descends; but by remaining fixed, shows distinctly, and very accurately, how high the mercury had risen, and consequently what degree of heat or cold had happened. Fig. 2. represents one of these indexes drawn larger than the real ones, to render it more distinct. *a* is a small glass tube, three quarters of an inch long, hermetically sealed at each end, inclosing a piece of steel wire nearly of the

Thermo-
meter.

same length; at each end *cd* is fixed a short piece of a tube of black glass, of such a diameter as to pass freely up and down within the small tube of the thermometer. The lower end floating on the surface of the mercury, is carried up with it when it rises, while the piece at the upper end being of the same diameter, keeps the body of the index parallel to the sides of the thermometer tube. From the upper end of the body of the index at *e* is drawn a spring of glass of the fineness of a hair, about five-sevenths of an inch in length, which being set a little oblique, presses lightly against the inner surface of the tube, and prevents the index from following the mercury when it descends, or being moved by the spirit passing up or down, or by any sudden motion given to the instrument by the hand or otherwise; but at the same time the pressure is so adjusted as to permit this index to be readily carried up by the surface of the rising mercury, and downwards whenever the instrument is to be rectified for observation. To prevent the spirit from evaporating, the tube at the end *i* is closely sealed (*n*). Fig. 3. represents the thermometer on its frame; the plates on which the scale is graven on either side are made to slide out, and the frame is open to the back behind the large tube, which does not touch it, except at each end. The cap *a*, and the base *b*, are made to fix on with screws, and only cover the turning of the small tube. By a screw at the bottom of the frame, it may be made fast to the wall against which it is to hang without doors, to prevent its being shaken by violent winds. Towards evening I usually visit my thermometer, and see at one view, by the index on the left side, the cold of the preceding night; and by that on the right, the heat of the day. These I minute down, and then apply a small magnet to that part of the tube against which the indexes rest, and move each of them down to the surface of the mercury: thus, without heating, cooling, separating, or at all disturbing the mercury, or moving the instrument, may this thermometer, without a touch, be immediately rectified for another observation. When I wish to put the thermometer out of my hand without hanging it up, I have a stand to place it on; for if the mercury presses against the index while the instrument lies in an horizontal position, it is in danger of passing by it, which is avoided by keeping the thermometer in a position nearly vertical. To prevent the mercury shifting its place in the spirits within the tube (which I apprehend it might do on account of the superiority of its specific gravity, especially when kept for a considerable time, very high on one side, and low on the other), I made that part of the small tube from *e* to *f* with the inner diameter exceeding small; and found upon trial, that after the summer's heat had kept the mercury for a long time high on one side, the winter's cold brought it again as accurately to the freezing point on the other as at first (*x*). This thermometer may be made a mercurial

"(c) The divisions below the freezing point are taken by means of a mixture of sea-salt and ice, as described by Nollet, De Luc, and others.

"(d) When this tube is closed (not hermetically, but only so as to prevent the spirits evaporating) the thermometer must be brought to the greatest heat it is likely at any time after to sustain: and though no more air is enclosed than what remains at that time above the spirits, yet that will, by its elasticity pressing on the fluid, answer every purpose as well as if the external air was freely admitted.

"(e) With a thermometer of this sort I observed the greatest heat and cold that happened every day and night throughout the year 1781.

rial one by inverting the glass, and filling with mercury that part which in the first is filled with spirits, and with spirits that part of the small tube from *d* to *g* which in the former is filled with mercury; the indexes in either case may be the same, and will be carried up in the same manner upon the surface of the mercury; but the end of the tube at *i*, instead of being sealed, must then be left open, and stand inverted in a bulb, or small cistern of mercury, into which the external air has free access. The diameter of the tube *ab* should be considerably increased if the degrees on the scale are required to be as wide as those in the spirit-thermometers. It is indeed better in this case to have a double rather than a larger single tube; but finding the weight of so great a quantity of mercury in a thin glass tube attended with many disadvantages, and the motion of the fluids in the spirit-ones perfectly agreeing with, and being as readily excited by change of heat and cold as in the mercurial thermometers, I preferred the former as much more commodious. A person cannot approach near to the thermometer first described when the air is very cold (especially with a light, which by night is necessary) without causing the spirits presently to expand, and consequently the mercury on the left side immediately to descend. This sensibility is here attended with every advantage, without the inconvenience to which common thermometers in this case are liable (*r*); for the index will accurately show the greatest height to which the mercury had risen, although, before the exact degree can well be distinguished, it will appear separated from the index, and descending space. As the scale is 16 inches long, and divided into 100° only, which are more than sufficient for the temperature of the air, they are large enough to be subdivided at pleasure. The indexes, though of a tender and delicate nature, when once placed in the tube, are not liable to suffer any alteration by time or accident; and the thermometer may be exposed to rain at all times, without suffering the least injury in any respect.

“ In constructing the thermometer before-mentioned, I at first hit on a plan by which the same end was obtained by a different method; and though in some respects, and for some purposes, it may not be so proper as that already described, yet for some others it may be found useful; and therefore I shall briefly describe it. The glass of this instrument is in all respects the same as in the former, excepting that the diameters of the tubes are something larger. It is likewise filled with spirits of wine and mercury, in the same manner; but the indexes are different, being only a small tube of black glass, about five-sevenths of an inch in length, hermetically sealed at each end, containing a piece of steel wire. An index of this sort is placed in the thermometer on either side, which ha-

ving no spring to support them, sink down in the spirits, and rest upon the mercury. Whenever the mercury descends, the index will follow it; but when it rises, the index will not rise with it, and by remaining at the place to which the mercury had descended, will show the greatest degree of heat or cold which had happened. In this manner do these indexes answer the same purpose, though they move directly contrary to the others in the other thermometer; but this instrument is not so easily rectified as the former, for the most powerful magnet will not bring the index up again while the mercury above presses against them; and although it is possible to remove the mercury, and by that means set the index at liberty, yet inconveniences will be incurred from which the other is entirely free.

“ In some cases it may be found expedient, instead of the double thermometer first described, to make two single ones; one to show the greatest degree of heat only, and the other the cold, each having its proper index (see fig. 4. and 5.). The first has the small tube as this thermometer was principally to be used immersed in a bulb or small cistern of mercury, to which the external air has free access; the other has the small tube turned up on the right side, with some mercury let down to the bottom, and the upper end closely sealed, as in the double instrument. Making a standard mercurial thermometer, by which the scale of the spirit-one was to be divided, I endeavoured to obtain as wide degrees as possible, that the motion of the mercury might thereby be rendered more conspicuous, and the height of it ascertained with greater precision. It is true, the larger the degrees, the larger in some measure must be the bulb, and therefore the fluid contained in it not likely to be so soon affected by any change bent down on the left side, and the lower end immersed in heat or cold in the atmosphere as in a smaller. But sed in a large quantity of water, gradually heating or cooling, little or no disadvantage could arise from making the bulb somewhat larger than those commonly made use of in the air. Not being able, however, to procure glass tubes so long as I had occasion for, whose inner diameters were perfectly equal, I took the following method to adjust the divisions on the scale to the inequality of the tubes. Choosing a tube of a length suitable to my purpose, with a proper bulb at the end, I put into it a small quantity of mercury (*c*) sufficient to form a column about one inch in length. Drawing then on a board the three lines *aa*, *bb*, *cc*, fig. 6. I placed the glass tube on the line *aa*, and while the mercury remained at rest at the end of the tube, near the bulb, I made two pencil-marks on the line *aa*, one at *d*, and the other at *e*, perfectly coinciding with the two ends of the column of mercury: then causing the mercury to move slowly on farther from the bulb, till that end of the column which was first at *d* coincided

“ (*r*) The most sensible mercurial thermometers commonly have the column of mercury, as well as the degrees, very small; and a person assisted with a light can hardly view them near enough, when the weather is very cold, without causing the mercury to rise before the degrees where it stood can be well ascertained.

“ Freezing fogs also, which with us usually attend the greatest degrees of cold, by covering the glass with frost, render the mercury invisible, and cannot well be removed without causing the mercury to rise, or at least render the observation doubtful, which at such a time is very disagreeable; for in proportion to the extraordinary degree of cold, so is our curiosity likely to be excited.

“ (*g*) To put in a small quantity of mercury, and measure its length at different parts of the tube, as described by Abbe Nollet, vol. iv. p. 370. *Leçons Physiques*, is a very excellent method to discover the error; but in what manner readily to adjust the scale so as to avoid any inaccuracy from such inequality (which in tubes of the length I had occasion for seemed to me unavoidable), was a matter concerning which I could meet with no information.

ded with the mark at *e*, and letting it rest again, I made another mark at *f*; after which, causing the mercury to move on as before, and continuing to mark its length at every part of the tube till it reached the end farthest from the bulb; by these means I obtained the several intermediate points on the line *aa*. Through these several points I drew dotted lines parallel to each other, and at right angles with the line *aa* to the line *bb*. Taking now, with a pair of compasses, the widest intervals between any of the dotted parallels, which in this case is from *d* to *e*, I inserted that distance successively between the several parallels, beginning at the lowest pair, as from *d* to *e*, from *e* to *f*, from *f* to *g*, and so on to *h*, as exhibited in the figure; and the aggregate of these lines may be considered as one continued line, without any error of consequence in this matter. Having now the thermometer completely filled with mercury, the air expelled, the point of the scale at 102°, and the freezing point properly taken (H) and marked upon the tube, which was now hermetically sealed, I again applied the tube to the line *aa*, and marked on that line the point of 102° and the freezing point. Through those points I drew the lines *ii*, *kk*, and divided that part of the compound line *db* included between *ii* and *kk* into 14 equal parts, beginning at *a*, the point where *ii* cuts the line *db*, continuing afterward six divisions now on that line below *kk*, making in all 20 equal divisions. If now lines be drawn through each of the dividing points, from *a* to 20 to the line *cc*, at right angles with the same, they will give on the line *cc* the true thermometrical scale to every 5° from 2 to 102, properly adjusted to the inequality of the tube (1), which in this case is nearly of the same diameter at each end, but smaller towards the middle. Tubes may indeed be found of some considerable length with less inequality than what this scale exhibits; but the error is here enlarged to render the method of correcting it more conspicuous."

Though Fahrenheit's thermometer is that most commonly used, yet as others have been invented by different persons, we have thought proper, in Plate CCLXXXV. to give a comparative view of their different scales; by which if the reader happens to meet with any of those instruments, or to peruse the accounts of observations made by them, they may be easily reduced to one standard.

THERMOPYLÆ, (anc. geog.); a narrow pass or defile, between the wash of the Sinus Maliacus; on the east and steep mountains, reaching to Oeta, made dreadful by unpassable woods; on the west, leading from Thessaly to Locris and Bœotia. These mountains divide Greece in the middle, in the same manner as the Apennine does Italy; forming one continued ridge from Leucate on the west to the sea on the east, with thickets and rocks interspersed; that persons even prepared for travelling, much

less an army encumbered with baggage, cannot easily find a commodious passage. In the valley verging towards the Sinus Maliacus, the road is only sixty paces broad; the only military way for an army to pass, if not obstructed by an enemy; and therefore the place is called *Payla*, and by others, on account of its hot water, *Thermopyla*. Ennobled by the brave stand made by Leonidas and three hundred Spartans, against the whole army of Persia; and by the bold resolution of blind Euthycus, choosing rather to fall there in fight, than return to Sparta, and escape the common danger. Famous also for the Amphyctiones, the common council, or states general of Greece, assembling theretwice a-year, spring and autumn.

THESEA, in antiquity, feasts celebrated by the Athenians in honour of Thefeus, consisting of sports and games, with mirth and banquets; such as were poor and unable to contribute to them were entertained at the public expence.

THESEUS, a famous hero of antiquity ranked among the demi-gods, whose history is fabulous. He was the reputed son of *Aegæus* king of Athens. He threw Sciron, a cruel robber, down a precipice; fastened Procrustes tyrant of Attica to a bending pine, which being let loose, tore him asunder; killed the Minotaur kept in the labyrinth by king Minos, in Crete; and by the assistance of that prince's daughter, Ariadne, who gave him a clue, escaped out of that labyrinth, and failed with his deliverer to the isle of Naxos, where he had the ingratitude to leave her.

Thefeus afterwards overcame the Centaurs, subdued the Thebans, and defeated the Amazons. He assisted his friend Pirithous in his expedition to the infernal regions to carry off Proserpine; but was imprisoned by Pluto, till he was released by Hercules. He is also said to have established the Isthmian games, in honour of Neptune; to have united the twelve cities of Attica; and to have founded a republic there, 1236 B. C. Some time after, taking a voyage into Epirus, he was seized by Aidonius king of the Molossians; meanwhile Menestheus rendered himself master of Athens. But at length Thefeus being released from prison, retired to Scyros, where king Lycomedes caused him to be thrown from the top of a rock. Thefeus had several wives; the first of whom was Helena the daughter of Tyndarus; the second, Hypolita queen of the Amazons; and the last, Phædra sister to Ariadne, who punished him for his infidelity to her sister, by her incestuous passion for his son Hippolitus.

THESIS, a general position which a person advances, and offers to maintain. In colleges it is frequent to have placards containing a number of them in theology, in medicine, in philosophy, in law, &c.

THESPIS, a famous Greek tragic poet, and the first representer of tragedy at Athens. He carried his

"(H) The freezing point marked on the tube of this thermometer is immediately taken by means of grated ice but the point of 100° by a standard mercurial thermometer, the upper point of the scale of which was properly taken by boiling water, and the lower one by grated ice; but it is more commodious in the first to have the tube no longer than the air-scale, especially as the degrees are pretty wide. The method of adjusting the scale to the inequality of the tube remains the same, let the given points be at any distance, or the divisions increased to any number.

"(I) Experimentally to prove this method, I have made mercurial thermometers, whose scales from the freezing point to that of boiling heat were nearly three feet; and though the inequalities of the tubes were very considerable, varying in contrary directions to each other, yet when they were on the same frame, they perfectly agreed in a motion of the mercury in every part of their scales."

Theffaly. his troop from village to village in a waggon, from which they performed their pieces. Alceſtis was the firſt tragedy they performed at Athens, 536 B. C.

THESSALY, a country of ancient Greece, ſuppoſed to have received its name from Theſſalus the father, or, according to others, the ſon of Græcus, an ancient king of an obſcure village, from whom the Greeks are ſaid to have been defended. It was alſo called *Emonia*, the origin of which name is uncertain; *Pelaſgia*, from Pelafgus one of the firſt Grecian princes; and *Pyrrhæa*, from Pyrrha the wife of Deucalion.

It was anciently divided into four diſtricts, or perhaps kingdoms. Theſſaliotes, Illeotis, Pelafgiotis, and Phthiotis. Deucalion was king of this laſt when the deluge that goes by his name happened, which deſtroyed all the inhabitants of this and the neighbouring countries, except only ſuch as happily eſcaped into the high mountains of Theſſaliotes, and Deucalion and his wife, who were carried in an ark upon the waters nine days and nights, and reſted at length upon Parnaſſus, from which they were ſeigned to have re-peopled the country by throwing of ſtones behind them. However, the name of Theſſaly and Theſſalians in time prevailed, and came to ſignify all the four parts. Sometimes it included Magnæſia and Phthiotis, and ſometimes not; ſometimes it was joined with Macedonia, and ſometimes ſepered from it, and again rejoined to it.

Theſſaly, properly ſo called, had on the eaſt the provinces of Magnæſia and Phthia above-mentioned, and theſe two were bounded by the *Ægean* ſea. On the weſt it had Illyricum and Epirus, now Albania; on the north Macedonia and Mygdonia, and on the ſouth Grecia Propria. It extended from 24 deg. 10 min. to 25 and a half eaſt longitude, and from north to ſouth, from 39 deg. 50 min. to about 41 deg. north latitude.

Theſſaly was famous, among other things, for ſuch an extraordinary breed of oxen, that Neleus king of Pylus reſuſed to give his daughter in marriage to Melampus king of Tyrius, except he procured him ſome of them; which he ſoon after did by the help of his brother Bias. What fine horſes they bred, and how expert they were in the uſe and management of that noble creature, is evident, ſince the fiction of the Centaurs is allowed to have taken its origin from them. This fable, however, reflects no leſs diſgrace upon them for their brutiſh incontinency, than it commends them for their skill in horſemanſhip. The attempt which they made upon the women at the nuptials of their neighbour Pirithous king of the Lapithæ, if not forged on purpoſe to caſt an ignominious brand upon them, is a pregnant proof of the one; and the hiſtory of their wars with other nations afford us a conſtant proof of the latter: ſo that in ſpite of their debauchery, they have ſhewed themſelves a warlike nation; and as ſuch, their alliance as well as aſſiſtance, eſpecially that of their cavalry, was ever highly courted by contending powers. And indeed, if we conſider how liable the pleaſantneſs and fertility of their country made them to foreign invaſions, it will be no wonder they ſhould be ſo well inured to the trade of war. Nor can it be ſuppoſed that any thing but their extraordinary valour could have ſaved them from being ſwallowed up by

ſome of their neighbours, conſidering that their ſcanty territories conſiſted only of four ſmall kingdoms or diſtricts, as often diſjoined from each other under different princes, as united together under one.

At the head of the Theſſalian hiſtory muſt be placed the celebrated Argonautic expedition, which happened in the reign of Pelias king of Theſſaly, about the year of the world 2720, or 100 years before the taking of Troy. The occaſion of this expedition was as follows:

Æſon the third in deſcent from *Æolus*, being either worn out with age or weary of government, whilst his ſon *Jaſon* was yet very young, appointed *Pelias*, his brother by the mother's ſide, guardian of the kingdom till his ſon came of age. *Pelias* on the other hand, who had reſolved to ſecure the government to himſelf, ſent to conſult the oracle about it, and was bid to beware of the man that had but one ſhoe. It happened ſome time after, that as he was ſacrificing to *Neptune*, he called his nephew to him, who was on the other ſide of a rivulet, and *Jaſon* having dropped one of his ſhoes in croſſing the brook, gave him occaſion to think that he was the perſon pointed out by the oracle. He then aſked him what courſe he would take with the perſon of whom the oracle had bid him beware; and *Jaſon* readily answered, That he would ſend him to *Colchis* in ſearch of the golden fleece. His uncle took him at his word, and ſent him immediately upon that enterpriſe. *Jaſon* made no difficulty to obey; and having engaged a conſiderable number of young noblemen, the flower of all Greece, to this expedition, he procured a ſhip to be built for this purpoſe at *Pegaſa*, by one *Argus*, from whom he called it *Argos*; and hence he and his gallant company were called *Argonautæ*.

Theſe adventurers, after many ſtrange difficulties and exploits, arrived at length at the land of *Colchis*, where the golden fleece was kept. They went immediately to the metropolis, where *Jaſon* acquainted *Æetes* king of the country with *Pelias's* command, and demanded the fleece of him. *Æetes* promiſed to deliver it to him, provided he could yoke together by his own ſingle ſtrength two fierce and terrible bulls (which had brazen hoofs, and breathed out fire and flame, and had been preſented to him by *Vulcan*), and plough the ground with them, ſowing it with the dragon's teeth which *Minerva* had given him, and were the remainder of thoſe which *Cadmus* had ſown at *Thebes*.

Jaſon, perplexed how to perform theſe conditions, was happily relieved by *Medea* the king's daughter, who was fallen in love with him. She promiſed him that if he would marry her, ſhe would aſſiſt him in it; and he had no ſooner agreed to it, than ſhe gave him a medicine, with which having anointed his body and armour, he became proof againſt the violence of the bulls; or, according to others, the taught him how to tame theſe fierce creatures, ſo as to be able to yoke and make uſe of them. She told him, moreover, that the teeth which he was to ſow would preſently ſpring up into armed men, which would infaſſibly deſtroy him unleſs he raiſed an immediate diſſention among them, by throwing ſtones at them, during which he might eaſily cut them off. *Jaſon* having ſucceſsfully performed the taſk, went and demanded the fleece according to *Æetes's* promiſe, whilst

Theſſaly. whilst he, instead of delivering it, was contriving how to destroy him and his company, and burn their ship. To prevent this, Medea went, and by her enchantments cast the dragon into a deep sleep, stole the fleece, and brought it to her lover, who took her, and, at her desire, also her brother Absyrtus, into his ship, and sailed away immediately with his companions. Æetes, who was soon informed of his daughter's treachery, pursued immediately after them; which when she perceived, she cut her brother in pieces, and scattered his mangled limbs about in hopes to stop his farther pursuit, as it actually did: for the disconsolate king, surprised at her unnatural barbarity, staid to gather up the fragments of his son's body, and buried them in a place called from thence *Toni*; and in the mean time she and the Argonauts escaped into *Theſſaly*, not without having first felt the effects of Jupiter's anger for the murder of Absyrtus, and after having spent four whole months in this expedition.

During the absence of Jason, Pelias, who never expected his return from Colchis, had taken some means to cut off his father, in order to fix the kingdom upon himself and his son Acastus; and the old king being apprised of his plots, had poisoned himself by drinking a draught of bull's blood. His queen likewise, oppressed with grief for his death, and the supposed loss of her son and kingdom, had hanged herself; so that Pelias now thought himself secure on his throne, when, contrary to his expectation, Jason returned successful and victorious, and brought the fleece to him. However, he had so well strengthened himself in it, that Jason did not dare to undertake any thing against him openly. Medea was forced to have recourse to her magic to be revenged on the tyrant, and, as some say, restored Jason's father to life. After this she persuaded Pelias's daughters to boil their old father, on pretence she would restore him to life and youthful vigour; but upon her non-performance Acastus mounted the throne, and having performed his father's funeral obsequies, banished Jason and his wife from *Theſſaly*, who went and dwelt at Corinth.

Acastus is famed for having been a great hunter, and for the incontinency of his wife Hippolyta, or, as she is called by others, *Cretheis*; which proved fatal to him. She was in love with Peleus the son of Cæus, and had solicited him in vain for some time, till, enraged at length at his constant refusal, she accused him to her husband for making some attempts upon her honour. Acastus believing her, and endeavouring to kill Peleus, was himself and his unchaste wife slain by him.

The next *Theſſalian* prince, both in time and fame, was the celebrated Achilles, the son of Peleus and Thetis, the goddess of the sea. This hero was king of Phthia, one of the four provinces of *Theſſaly*, and is feigned to have been dipped by his mother in the river Styx when he was a child, and to have been made invulnerable by it in every part except the heel, by which she held him. After this she sent him to be brought up by the Centaur Chiron, where he learned music, arms, and the riding of the great horse. Being afterwards warned by the oracle, that if he went to the Trojan war he should meet with his death there, she dispatched him privately in woman's apparel to Lyco-

medes king of Scyrus, an island in the *Ægean* sea, and one of the Cyclades.

In the mean time the Grecian chiefs, being likewise forewarned by an old prophecy, that their enterprise against Troy would prove unsuccessful unless they had Achilles with them, Ulysses undertook to find him out, and to bring him to that war; which he accordingly did. Thetis finding that her son was determined to prefer a glorious death before the walls of Troy to an inglorious immortality, prevailed upon Vulcan to make him an impenetrable armour, with which he went at the head of his bold myrmidons to the fatal siege. Here he forbore acting for some time, upon a pique he had taken against Agamemnon on account of a beautiful female captive; but his resentment giving way to his grief for the death of his dear friend Patroclus, who had been killed by Hector, Achilles thenceforth fought nothing but to revenge it; which he soon after did. Hector was not only slain, but most barbarously used by him after his death, he having caused his body to be tied to his chariot and dragged thrice round the walls of Troy. This inhumanity did not go long unpunished; and Priam having redeemed his son's shattered remains at an excessive price, Paris, another of his sons, soon after shot Achilles in the heel, the only place in which he was not invulnerable.

The two most memorable things which the *Theſſalians* are since recorded for, are their driving the *Beotians* from the country of Arne, a small territory in *Theſſaly*; so called from its metropolis built by *Beotus* the son of Neptune, by Arne the daughter of *Æolus*, the second of that name, who was the son of Hypotes, and grandson of Mimas king of *Æolis*; and their constant wars against the *Phocians*. The former of these happened, according to Thucydides, 60 years after the taking of Troy, and about 100 after their first settlement in that territory; when the *Beotians* being driven thence, went and possessed themselves of a country then named *Cadmeis*, and called it by their name *Boeotia*. We have elsewhere spoken of that country, and given another etymology of it, to which we refer the reader.

As for their wars with the *Phocians*, it is not easy to guess at the true ground of them; only we find, that there was an irreconcilable hatred entailed between those two nations, which proved a constant source of fresh and bloody encounters, in which the *Theſſalians*, though superior in strength, especially on account of their cavalry, were very often worsted by the policy of their enemies; witness those statues of Apollo, Minerva, Diana, and other trophies, which Pausanias tells us they set up both on their borders and at the temple of Delphos, in memory of their signal victories over them. The truth is, the kingdom of Phocis was very mountainous, and the avenues to it very rugged; so that the *Theſſalians*, who seem still to have been the aggressors, could receive but little benefit from their horse.—*Theſſaly* is now called *Fanna*, a province of European Turkey, bounded by Macedonia on the north, by the Archipelago on the east, by Achaia or Livadia on the south, and by Epirus on the west.

THETIS, in Pagan mythology, the wife of Oceanus, and the mother of Nereus and Doris, who were married

Theſſaly,
Thetis.

Thevenot,
Thibet.

married to each other; and from this marriage sprung the nymphs of the earth and sea. Among the sea-nymphs there was one named *Thetis* the *Younger*, who excelled all the rest in beauty, and for whom Jupiter conceived such a passion, that he resolved to espouse her; but being informed by the Destinies that she would bring forth a son who would rise above his father, he married her to Peleus. To their nuptials all the gods and goddesses were invited, except Discord, who, to be revenged for this contempt, threw a golden apple into the assembly, on which was engraven, *This for the fairest*. Juno, Pallas, and Venus, disputed for this apple; but Paris being chosen to decide the difference, adjudged it to Venus. From the marriage of Thetis and Peleus sprung Achilles.

THEVENOT (Melchisedeck), a celebrated writer of travels, and keeper of the French king's library, was born at Paris. At a very early period he discovered an extreme desire to see foreign countries; and notwithstanding the intreaties of his mother, who strove to detain him, he set out from Paris on his travels. However, he visited only a part of Europe; but the study of the languages of different countries, and the great pains he took to obtain a knowledge of their manners and customs, rendered him, perhaps, as well skilled in them as if he had himself travelled in those countries. He collected a great number of curious manuscripts in English, French, Spanish, Italian, Latin, Greek, Hebrew, Syriac, Arabic, Turkish, and Persian. He applied himself to study during his whole lifetime; and his Travels into the Levant are esteemed. They were published in folio, in French, in 1663, and in English in 1687.

THIBET, a country of Asia, very little known to the Europeans, till of late that it has been in some measure explored by Mr Bogle, one of the servants of the English East India Company. In Bengal this country is known by the name of *Boutan*, and lies to the northward of Hindostan, separated from it by a range of high and steep mountains, properly a continuation of the celebrated mount Caucasus. This chain of mountains stretches from the ancient Media and the shores of the Caspian Sea, round the north-east frontiers of Persia to Candahar and Cassamire; from thence directing its course more easterly, it forms the great northern barrier to the various provinces of the Mogul empire, and probably ends in Affam or China. In the valleys lying between the lower mountains are many tribes of Indian people; and a dispute happening between the heirs of one of the rajahs or petty princes, one party called to their assistance the Boutaners, and the other the British. The latter prevailed; and the fame of British valour being carried to the court of Thibet, the *Tayshoo-Lama*, who ruled the state under the Delai-Lama, at that time in his minority, sent a deputation to Bengal, desiring peace for the prince who had been engaged in war with the British. This was readily granted by the governor; and Mr Bogle was sent ambassador to the court of Thibet, where he resided several months; and after an absence of a year and a quarter, returned to Calcutta. The account of this gentleman's expedition hath not been published by himself; but from Mr Stewart's letter to Sir John Pringle, published in the Philosophical Transactions, vol. 67. we learn the fol-

lowing particulars, collected from his papers.

"Mr Bogle divides the territories of the Delai Lama into two different parts. That which lies immediately contiguous to Bengal, and which is called by the inhabitants *Doocho*, he distinguishes by the name of *Boutan*; and the other, which extends to the northward as far as the frontiers of Tartary, called by the natives *Pu*, he styles *Thibet*. Boutan is ruled by the Dah Terriah, or Deb Rajah, as I have already remarked. It is a country of steep and inaccessible mountains, whose summits are crowned with eternal snow; they are intersected with deep valleys, through which pour numberless torrents that increase in their course, and at last, gaining the plains, lose themselves in the great rivers of Bengal. These mountains are covered down their sides with forests of stately trees of various sorts; some (such as pines, &c.) which are known in Europe; others, such as are peculiar to the country and climate. The valleys and sides of the hills which admit of cultivation are not unfruitful, but produce crops of wheat, barley, and rice. The inhabitants are a stout and warlike people, of a copper complexion, in size rather above the middle European stature, hasty and quarrelsome in their temper, and addicted to the use of spirituous liquors; but honest in their dealings, robbery by violence being almost unknown among them. The chief city is Tasly Seddein situated on the Patchoo. Thibet begins properly from the top of the great ridge of the Caucasus, and extends from thence in breadth to the confines of Great Tartary, and perhaps to some of the dominions of the Russian empire. Mr Bogle says, that having once attained the summit of the Boutan mountains, you do not descend in an equal proportion on the side of Thibet; but continuing still on a very elevated base, you traverse valleys which are wider and not so deep as the former, and mountains that are neither so steep, nor apparently so high. On the other hand, he represents it as the most bare and desolate country he ever saw. The woods, which every where cover the mountains in Boutan, are here totally unknown; and, except a few straggling trees near the villages, nothing of the sort to be seen. The climate is extremely severe and rude. At Chamnanning, where he wintered, although it be in latitude $31^{\circ} 39'$, only 8° to the northward of Calcutta, he often found the thermometer in his room at 29° under the freezing point by Fahrenheit's scale; and in the middle of April the standing waters were all frozen, and heavy showers of snow perpetually fell. This, no doubt, must be owing to the great elevation of the country, and to the vast frozen space over which the north wind blows uninterruptedly from the pole, through the vast deserts of Siberia and Tartary, till it is stopped by this formidable wall.

"The Thibetians are of a smaller size than their southern neighbours, and of a less robust make. Their complexions are also fairer, and many of them have even a ruddiness in their countenances unknown in the other climates of the east. Those whom I saw at Calcutta appeared to have quite the Tartar face. They are of a mild and cheerful temper; and Mr Bogle says, that the higher ranks are polite and entertaining in conversation, in which they never mix either strained compliments or flattery. The common people, both

Thibet.

in Boutan and Thibet, are clothed in coarse woollen stufts of their own manufacture, lined with such skins as they can procure; but the better orders of men are dressed in European cloth, or China silk, lined with the finest Siberian furs. The ambassador from the Deb Rajah, in his summer-dress at Calcutta, appeared exactly like the figures we see in the Chinese paintings, with the conical hat, the tunic of brocaded silk, and light boots. The Thibetian who brought the first letter from the Lama was wrapped up from head to foot in furs. The use of linen is totally unknown among them. The chief food of the inhabitants is the milk of their cattle, prepared into cheese, butter, or mixed with the flour of a coarse barley or of pease, the only grain which their soil produces; and even these articles are in a scanty proportion: but they are furnished with rice and wheat from Bengal and other countries in their neighbourhood. They also are supplied with fish from the rivers in their own and the neighbouring provinces, salted and sent into the interior parts. They have no want of animal-food from the cattle, sheep, and hogs, which are raised on their hills; and are not destitute of game, though I believe it is not abundant. They have a singular method of preparing their mutton, by exposing the carcass entire, after the bowels are taken out, to the sun and bleak northern winds which blow in the months of August and September, without frost, and so dry up the juices and parch the skin, that the meat will keep uncorrupted for the year round. This they generally eat raw, without any other preparation. Mr Bogle was often regaled with this dish, which, however unpalatable at first, he says, he afterwards preferred to their dressed mutton just killed, which was generally lean, tough, and rank. It was also very common for the head men in the villages through which he passed, to make him presents of sheep so prepared, set before him on their legs as if they had been alive, which at first had a very odd appearance.

"The religion and political constitution of this country, which are intimately blended together, would make a considerable chapter in its history. It suffices for me to say, that at present, and ever since the expulsion of the Eluth Tartars, the kingdom of Thibet is regarded as depending on the empire of China, which they call *Cathay*; and there actually reside two mandarines, with a garrison of a thousand Chinese, at Lahassa the capital, to support the government; but their power does not extend far: and in fact the lama, whose empire is founded on the surest grounds, personal affection and religious reverence, governs every thing internally with unbounded authority. Every body knows that the Delai Lama is the great object of adoration for the various tribes of heathen Tartars, who roam through the vast tract of continent which stretches from the banks of the Volga to Corea on the sea of Japan, the most extensive religious dominion, perhaps, on the face of the globe. He is not only the sovereign pontiff, the viceregent of the Deity on earth; but, as superstition is ever the strongest where it is most removed from its object, the more remote Tartars absolutely regard him as the Deity himself. They believe him immortal, and endowed with all knowledge and virtue. Every year they come up from different parts, to worship and make rich offerings at his shrines:

VOL. X.

even the emperor of China, who is a Mantchou Tartar, does not fail in acknowledgments to him in his religious capacity; and actually entertains at a great expence, in the palace of Pekin, an inferior lama, deputed as his nuncio from Thibet. It is even reported that many of the Tartar chiefs receive certain presents, consisting of small portions of that, from him, which is ever regarded in all other persons as the most humiliating proof of human nature and of being subject to its laws, and treasure it up with great reverence in gold boxes, to be mixed occasionally in their ragouts. It is, however, but justice to declare, that Mr Bogle strenuously insists, that the lama never makes such presents; but that he often distributes little balls of consecrated flour, like the *pain benit* of the Roman-Catholics, which the superstition and blind credulity of his Tartar votaries may afterwards convert into what they please. The orthodox opinion is, that when the grand lama seems to die, either of old age or of infirmity, his soul in fact only quits an actual crazy habitation to look for another younger or better, and it is discovered again in the body of some child, by certain tokens known only to the lamas or priests, in which order he always appears. The present Delai Lama is an infant; and was discovered only a few years ago by the Tayhooh Lama, who in authority and sanctity of character is next to him, and consequently, during the other's minority, acts as chief. The lamas, who form the most numerous as well as the most powerful body in the state, have the priesthood entirely in their hands; and, besides, fill up many monastic orders, which are held in great veneration among them. Celibacy, I believe, is not positively enjoined to the lamas; but it is held indispensable for both men and women who embrace a religious life: and indeed their celibacy, their living in communities, their cloisters, their service in the choirs, their strings of beads, their fasts, and their penances, give them so much the air of Christian monks, that it is not surprising an illiterate capuchin should be ready to hail them brothers, and think he can trace the features of St Francis in every thing about them. It is an old notion, that the religion of Thibet is a corrupted Christianity; and even Father Disederii, a Jesuit (but not of the Chinese mission) who visited the country about the beginning of this century, thinks he can resolve all their mysteries into ours; and asserts, with a truly mystical penetration, that they have certainly a good notion of the Trinity, since, in their address to the Deity, they say as often *konciok-sik* in the plural as *konciok* in the singular, and with their rosaries pronounce these words, *om, ha, hum*. The truth is, that the religion of Thibet, from whence-ever it sprang, is pure and simple in its source, conveying very exalted notions of the Deity, with no contemptible system of morality: but in its progress it has been greatly altered and corrupted by the inventions of worldly men; a fate we can hardly regret in a system of error, since we know that that of truth has been subject to the same. Polygamy, at least in the sense we commonly receive the word, is not in practice among them: but it exists in a manner still more repugnant to European ideas; I mean in the plurality of husbands, which is firmly established and highly respected there. In a country where the means of subsisting a family are not easily

Thibet
Thistle.

found, it seems not impolitic to allow a set of brothers to agree in raising one, which is to be maintained by their joint efforts. In short, it is usual in Thibet for the brothers in the family to have a wife in common, and they generally live in great harmony and comfort with her; not but sometimes little dissensions will arise (as may happen in families constituted upon different principles) an instance of which Mr Bogle mentions in the case of a modest and virtuous lady, the wife of half a dozen of the Tayhoos Lama's nephews, who complained to the uncle that the two youngest of her husbands did not furnish that share of love and benevolence to the common stock which duty and religion required of them. In short, however strange this custom may appear to us, it is an undoubted fact that it prevails in Thibet in the manner I have described.

"The manner of bestowing their dead is also singular: they neither put them in the ground like the Europeans, nor burn them like the Hindoos; but expose them on the bleak pinnacle of some neighbouring mountain, to be devoured by wild beasts and birds of prey, or wafted away by time and the vicissitudes of weather in which they lie. The mangled carcases and bleached bones lie scattered about; and, amidst this scene of horror, some miserable old wretch, man or woman, left to all feelings but those of superstition, generally sets up an abode, to perform the dismal office of receiving the bodies, assigning each a place, and gathering up the remains when too widely dispersed."

THIGH, in anatomy. See ANATOMY, n° 57.

THINKING, a general name for any act or operation of the mind. See METAPHYSICS, n° 70.

THIRLAGE. See LAW, N° clxx. 12—18.

THIRST, an uneasy sensation arising from a deficiency of the saliva to moisten the inward parts of the mouth. Hence arises a strong desire for drink; and thirst is a symptom generally attending fevers of all kinds.—Thirst is best allayed by acids; water kept a while in the mouth, then spit out, and repeated as required; a bit of bread chewed with a little water, which latter may be gradually swallowed; if the person is very hot, brandy is the best for holding in the mouth, but should be spit out again: except in fevers, large draughts of cold water are hurtful.

Preservation against Hunger and Thirst. See HUNGER.

THISTLE, in botany. See CARDUS.—The dried flowers of the cardus lanceolatus or spear-thistle, and cardus nutans or milk-thistle, are used in some countries as a rannet for curdling their milk. Many kinds of phalene are fond of the flowers, and hover over them at night; the tender stalks of the palustris or marsh-thistle, and indeed of most thistles, are esculent, being first peeled and boiled. In this manner the inhabitants of Smaland in Sweden, as Linnaeus informs us, often eat them.

Order of the THISTLE, or of St Andrew, a military order of knighthood in Scotland, the rise and institution whereof is variously related by different authors. Lesley bishop of Ross reports, that the night before the battle between Athelstan king of Northumberland, and Hungus king of the Picts, a bright cross, in form of that whereon St Andrew (the tutelary saint of Scotland) suffered martyrdom, appeared to Hungus; who having gained the victory, ever after bore the figure

of that cross on his banners. Others assert, that Achaius king of Scotland first instituted this order, after having made the famous league offensive and defensive with Charlemagne king of France. But although the thistle had been acknowledged as the symbol of the kingdom of Scotland from the reign of Achaius, yet some refer the beginning of this order to Charles VII. of France. Others place the foundation of it as low as the year 1500.

The chief and principal ensign is a gold collar composed of thistles and sprigs of rue interlinked with amulets of gold, having pendent thereunto the image of St Andrew with his cross, and the motto, NEMO ME IMPUNE LACESSET.

The ordinary or common ensign worn by the knights, is a star of four silver points, and over them a green circle, bordered and lettered with gold, containing the said motto, and in the centre is a thistle proper; all which is embroidered on their left breast, and worn with the collar, with a green ribband over the left shoulder, and brought under the right arm; pendent thereto is the image of St Andrew, with his cross, in a purple robe, within an oval of gold enamelled vert, with the former motto: but sometimes they wear, encircled in the same manner, a thistle crowned.

About the time of the Reformation, this order was dropped, till James II. of England resumed it, by creating eight knights: however, the Revolution unsettled it again; and it lay neglected, till queen Anne, in 1703, restored it to the primitive design, of twelve knights of St Andrew.

THLASPI, MITHRIDATE, or *Treacle mustard*; a genus of the filiculosa order, belonging to the tetradynamia class of plants. There are 10 species; of which the most remarkable are, 1. The arvensis, or penny-cress, is a native of several places of England and Scotland, growing in corn-fields, but not very common. The stalk is a foot high, angular and branched; the leaves sessile, embracing the stalk at their base; the flowers very small and white. The plant smells of garlic; and in countries where it abounds, is found often to communicate its disagreeable odour to the milk of cows that feed on it. The seeds abound with an oil formerly used for the rheumatism and sciatica, but now taken no notice of. 2. The burra pastoris, or shepherd's purse, is common in corn-fields, gardens, waste places, and by waysides. This plant affords us a strong instance of the influence of soil and situation; for in some places it is not more than two inches high when it flowers and perfects its seeds, in others it rises to the height of two or three feet. It is infusid; but was nevertheless formerly much recommended in hæmorrhages of all kinds, though deservedly rejected in the present practice.

THOMASANS, THOMISTS, or *Christians of St Thomas*, a people of the East Indies, who, according to the tradition, received the Gospel from St Thomas. Upon the arrival of the Portuguese at Calicut, in their first voyage to the Indies, they met with ancient Christians, who pretended to be defended from those converted by St Thomas. The Thomæans being informed of a new people arrived among them, who bore a particular veneration for the cross, sent ambassadors to them to make an alliance with them, and to solicit their assistance against the Gentile princes, by whom

they

Thomazans they were greatly oppressed. A mixture of opinions, with a total interruption of pastors, sometimes for several years together, occasioned that horrible chaos their religion was in at the arrival of the Portuguese; for a specimen whereof we shall add their manner of celebrating the eucharist: Over their altar was a kind of gallery; and while the priest was saying the beginning of the office below, a cake of flour of rice was frying in oil, or butter, above; when enough, the cake was let down in a basket upon the altar, where the priest consecrated it: as to the other species, for wine they used a kind of brandy or arrack, variously prepared in that country. Nor was their ordination much more regular; the archdeacon, who was sometimes more respected than the bishop himself, frequently ordained priests: their other abuses were infinite. The Portuguese, for these two last centuries, have laboured both the ecclesiastical and secular power therein: for this end they have called the Thomazan bishops to the council at Goa, have instructed, charged them, &c. and even sent them for instruction to Portugal and Rome; but finding that they were still apt to relapse at their return, and that no good was like to be done with them, they resolved to exclude them once for all, and to appoint an European bishop in their room. These proceedings have rendered the Portuguese infinitely odious to the Thomazans.

St THOMAS the Apostle, furnished *Didymus*. He was not with the disciples when Christ appeared to them after his resurrection, and therefore would not believe that he was really risen from the dead; but eight days after, Christ making him feel the place where the wounds had been made in his side and in his hands, he was thoroughly convinced of that important truth. His infidelity, indeed, furnished such an incontestible proof of our Saviour's resurrection, that it made some of the fathers say, that "St Thomas's incredulity was of greater service than the faith of the other apostles." St Thomas preached the gospel to the Ethiopians, Parthians, Medes, &c. It is even said that he preached to the Indians; and was run through with a lance, near the town of Meliapore, called the *town of St Thomas*: but this is now generally allowed to be a mistake, and the conversion of the people called the *Christians of St Thomas*, is, with great certainty, attributed to another Thomas, who lived five centuries after the apostle of that name.

St THOMAS, a city of the Hither India, on the coast of Coromandel, three miles south of Fort St George; subject to the Portuguese.

St THOMAS, is also an island in the Atlantic ocean, situated under the equator, in 8° E. Long.

St THOMAS is also a town of Guiana, in South America, situated on the river Oroonoko; subject to Spain.

St THOMAS's Day, a festival of the Christian church, observed on Dec. 21. in commemoration of St Thomas the apostle.

St THOMAS of Canterbury's Day, a festival of the Romish church, observed on Dec. 29. in memory of Thomas Becket archbishop of Canterbury, who was murdered, or, as the Romanists say, martyred, in the reign of king Henry II.

THOMISM, the doctrine of St Thomas Aquinas,

and his followers the Thomists, chiefly with regard to predestination and grace. There is some doubt what the true genuine Thomism is; but there are authors who distinguish the Thomism of St Thomas from that of the Dominicans. Others again make Thomism no other than a kind of Janfenism disguised: but Janfenism, it is known, has been condemned by the popes, which pure Thomism never was: in effect, the writings of Alvarez and Lemos, who were appointed by their order to lay down and defend, before the holy see, the dogmata of their school, have since been reputed the rule of pure Thomism.

THOMSON (James), an excellent British poet, the son of a Scots divine, was born in the shire of Roxburgh in 1700, and was educated in the university of Edinburgh with a view to the ministry. But his genius inclining him to the study of poetry, which he soon found would be incompatible with that of theology, or at least might prevent his being provided for in that way in his own country, he relinquished his views of engaging in the sacred function; and repaired to London in consequence of some encouragement he had received from a lady of quality there, a friend of his mother's.

The reception he met with wherever he was introduced, emboldened him to risk the publication of his excellent poem on Winter.—This piece was published in 1726; and from the universal applause it met with, Mr Thomson's acquaintance was courted by people of the first taste and fashion. But the chief advantage which it procured him, was the acquaintance of Dr Rundle, afterward bishop of Derry, who introduced him to the late lord chancellor Talbot; and some years after, when the eldest son of that nobleman was to make his tour of travelling, Mr Thomson was chosen as a proper companion for him. The expectations which his *Winter* had raised, were fully satisfied by the successive publications of the other seasons: of Summer, in the year 1727; of Spring, in the following year; and of Autumn, in a quarto edition of his works, in 1730. Beside the Seasons, and his tragedy of Sophonisba, written and acted with applause in the year 1729, he had, in 1727, published his poem to the memory of Sir Isaac Newton, with an account of his chief discoveries; in which he was assisted by his friend Mr Gray, a gentleman well versed in the Newtonian philosophy. That same year the resentment of our merchants, for the interruption of their trade by the Spaniards in America, running very high, Mr Thomson zealously took part in it, and wrote his spirited and public-spirited *Britannia*, to rouse the nation to revenge.

With the Hon. Mr Charles Talbot, our author visited most of the courts in Europe, and returned with his views greatly enlarged; not of exterior nature only, and the works of art; but of human life and manners, and of the constitution and policy of the several states, their connections, and their religious institutions.—How particular and judicious his observations were, we see in his poem on Liberty, begun soon after his return to England. We see at the same time, to what a high pitch his care of his country was raised, by the comparisons he had all along been making of our happy government with those of other nations. To inspire his fellow-subjects with the like sentiments, and

Thomson. show them by what means the precious freedom we enjoy may be preserved, and how it may be abused or lost, he employed two years in composing that noble work; upon which he valued himself more than upon all his other writings. On his return to England with Mr Talbot (who soon after died), the chancellor made him his secretary of briefs; a place of little attendance, suiting his retired indolent way of life, and equal to all his wants. This place fell when death, not long after, deprived him of his noble patron, and he then found himself reduced to a state of precarious dependence, in which he passed the remainder of his life; excepting only the two last years of it, during which he enjoyed the place of surveyor-general of the Leeward-islands, procured for him by Lord Lyttelton. His genius, however, could not be suppressed by any reverse of fortune. He resumed his usual cheerfulness, and never abated one article in his way of living; which, though simple, was genial and elegant. The profits arising from his works were not inconsiderable; his tragedy of Agamemnon, acted in 1738, yielded a good sum. But his chief dependence was upon the late prince of Wales, who settled on him a handsome allowance, and honoured him with many marks of particular favour. Notwithstanding this, however, he was refused a licence for his tragedy of Edward and Eleanor, which he had prepared for the stage in the year 1739.

Mr Thomson's next performance was the Masque of Alfred, written jointly with Mr Mallet, by the command of the prince of Wales, for the entertainment of his royal highness's court, at Clifden, his summer-residence, in the year 1740. Mr Thomson's poem, entitled the *Casile of Indolence*, was his last work published by himself; his tragedy of Coriolanus being only prepared for the theatre, when a fatal accident robbed the world of one of the best of men and best of poets. He would commonly walk the distance between London and Richmond (where he lived), with any acquaintance that offered, with whom he might chat and rest himself, or perhaps dine by the way. One summer evening being alone in his walk from town to Hammer-smith, he had over-heated himself, and in that condition imprudently took a boat to carry him to Kew; apprehending no bad consequence from the chill air on the river, which his walk to his house, towards the upper end of Kew-lane, had always hitherto prevented. But now the cold had so seized him, that the next day he found himself in a high fever. This, however, by the use of proper medicines, was removed, so that he was thought to be out of danger; till the fine weather having tempted him to expose himself once more to the evening dews, his fever returned with violence, and with such symptoms as left no hopes of a cure. His lamented death happened on the 27th of August 1748.

Mr Thomson had improved his taste upon the finest originals, ancient and modern. The autumn was his favourite season for poetical composition, and the deep silence of the night he commonly chose for his studies. The amusement of his leisure-hours were civil and natural history, voyages, and the best relations of travellers. Though he performed on no instrument, he was passionately fond of music, and would sometimes listen a full hour at his window to the nightingales in

Richmond gardens; nor was his taste less exquisite in the arts of painting, sculpture, and architecture. As for the more distinguishing qualities of his mind and heart, they best appear in his writings. There his devotion to the Supreme Being, his love of mankind, his country, and friends, shine out in every page; his tenderness of heart was so unbounded, that it took in even the brute creation. It is not known, that through his whole life he ever gave any person a moment's pain, either by his writings or otherwise. He took no part in the political squabbles of his time, and was therefore respected and left undisturbed by both sides. These amiable virtues did not fail of their due reward; the applause of the public attended all his productions, and his friends loved him with an enthusiastic ardour.

His testamentary executors were the Lord Lyttelton, whose care of our poet's fortune and fame ceased not with his life; and Mr Mitchell, a gentleman equally noted for the truth and constancy of his private friendship, and for his address and spirit as a public minister. By their united interests, the orphan play of Coriolanus was brought on the stage to the best advantage; from the profits of which, and the sale of manuscripts and other effects, a handsome sum was remitted to his sisters. His remains were deposited in the church of Richmond, under a plain stone, without any inscription. A handsome monument was erected to him in Westminster abbey, in the year 1762, the charge of which was defrayed by the profits arising from a splendid edition of all his works in quarto; Mr Millar the bookseller, who had purchased all Mr Thomson's copies, giving up his property on this grateful occasion.

THORN, a town of Poland, in Regal Prussia, and in the palatinate of Culm. It was formerly an Hanseatic town, and still enjoys great privileges; is large and well fortified; but part of the fortifications, and a great number of houses, were ruined by the Swedes in 1703. It is seated on the Vistula, in E. Long. 19. 22. N. Lat. 52. 56.

THORNBACK, in ichthyology. See RAIA.

THORNHILL (Sir James), an eminent English painter, was born in Dorsetshire in 1676, of an ancient family; but was constrained to apply to some profession by the distresses of his father, who had been reduced to part with his family-estate. His genius directed him to the art of painting, which his uncle Dr Sydenham enabled him to study by placing him with a middling painter; however, his own talents supplied the deficiencies of his instructor; and by a happy exertion of them, he gradually rose to the highest reputation. The dome of St Paul's church at London, with his works at Hampton-court and Greenwich hospital, are public proofs of his merit that will convey his name to posterity with the greatest honour. He enriched himself so far by his works that he purchased back his paternal estate; was appointed state-painter to queen Anne, received the honour of knighthood, and was several years a member of parliament. He died in 1732.

THOROUGH-WAX, in botany. See BUPLEURUM.

THOUGHT, a general name for all the ideas consequent on the operations of the mind, and even on the operations themselves. See METAPHYSICS.

THOUGHT, in composition, See ORATORY, n° 101, 104, 111.

When

Thomson
Thought.

Thought.

When speaking with a particular reference to the belles letters and polite arts, we mean, by thoughts, the ideas which the artist attempts, to raise by his performance, in contradistinction to the manner in which they are raised or expressed.

In works of art, thoughts are what remains of a performance, when stripped of its embellishments. Thus, a poet's thoughts are what remains of his poems, independently of the verification, and of some ideas merely serving for its decoration and improvement.

Thoughts, therefore, are the materials proposed and applied by art to its purposes: The dress in which they appear, or the form into which they are moulded by the artist, is merely accidental. Consequently, they are the first object of attention in every work of art; the spirit, the soul of a performance, which, if its thoughts are indifferent, is but of little value, and may be compared to a palace of ice, raised in the most regular form of an habitable structure, but, from the nature of its materials, totally useless.

While, therefore, you are contemplating an historical picture, try to forget that it is a picture: forget the painter, whose magic art has, by lights and shades, created bodies where there are none. Fancy to yourself that you are actually looking at men, and then attend to their actions. Observe whether they are interesting; whether the persons express thoughts and sentiments in their faces, attitudes, and motions; whether you may understand the language of their air and gestures, and whether they tell you something remarkable. If you find it not worth your while to attend to the persons thus realised by your fancy, the painter has thought to little purpose.

Whilst listening to a musical performance, try to forget that you are hearing sounds of an inanimate instrument, produced only by great and habitual dexterity of lips or fingers. Fancy to yourself, that you hear a man speaking some unknown language, and observe whether his sounds express some sentiments; whether they denote tranquillity or disturbance of mind, soft or violent, joyful or grievous affections; whether they express any character of the speaker; and whether the dialect be noble or mean. If you cannot discover any of these requisites, then pity the virtuoso for having left so much ingenuity destitute of thought.

In the same manner we must also judge of poems, especially of the lyric kind. That ode is valuable which, when deprived of its poetical dress, still affords pleasing thoughts or images to the mind. Its real merit may best be discovered by transposing it into simple prose, and depriving it of its poetical colouring. If nothing remains that a man of sense and reflection would approve, the ode, with the most charming harmony and the most splendid colouring, is but a fine dress hung round a man of straw. How greatly then are those mistaken, who consider an exuberant fancy and a delicate ear as sufficient qualifications for a lyric poet!

It is only after having examined the thoughts of a performance in their unadorned state, that we can pronounce whether the attire, in which they have been dressed by art, fits and becomes them well or ill. A thought, whose value and merit cannot be estimated but from its dress, is, in effect, as futile and insignifi-

cant as a man who affects to display his merit by external pomp.

THRACE, a country very frequently mentioned by the Greek and Latin writers, deriving its name, according to Josephus, from Tiras one of the sons of Japhet. It was bounded on the north by mount Hæmus; on the south, by the Ægean Sea; on the west by Macedon, and the river Strymon; and on the east by the Euxine Sea, the Hellespont, and the Propontis.—The Thracian Cherfonesus is a peninsula inclosed on the south by the Ægean Sea, on the west by the gulf of Melas, and on the east by the Hellespont; being joined on the north to the continent by a neck of land about 37 furlongs broad. The inland parts of Thrace are very cold and barren, the snow lying on the mountains the greatest part of the year; but the maritime provinces are productive of all sorts of grain and necessities for life; and withal so pleasant, that Mela compares them to the most fruitful and agreeable countries of Asia.

The ancient Thracians were deemed a brave and warlike nation, but of a cruel and savage temper; being, according to the Greek writers, quite strangers to all humanity and good-nature. It was to the Thracians, however, that the Greeks were chiefly indebted for the polite arts that flourished among them; for Orpheus, Linus, Musæus, Thamyras, and Eumolpus, all Thracians, were the first, as Eustathius informs us, who charmed the inhabitants of Greece with their eloquence and melody, and persuaded them to exchange their fierceness for a sociable life and peaceful manners; nay, great part of Greece was anciently peopled by Thracians. Tereus, a Thracian, governed at Daulis in Phocis, where the tragical story of Philomela and Progne was acted. From thence a body of Thracians passed over to Eubœa, and possessed themselves of that island. Of the same nation were the Aones, Tembices, and Hyanthians, who made themselves masters of Bœotia; and great part of Attica itself was inhabited by Thracians, under the command of the celebrated Eumolpus. It is not therefore without the utmost ingratitude and injustice that the Greeks style them *Barbarians*, since to them chiefly they were indebted both for the peopling and polishing of their country.

Thrace was anciently divided into a number of petty states; which were first subdued by Philip of Macedon. On the decline of the Macedonian empire, the country fell under the power of the Romans. It continued under subjection to them till the irruption of the Turks, in whose hands it still remains.

THRAVE, *or* CORN, an expression denoting 24 sheaves, or four shocks of six sheaves to the shock; though in some countries they only reckon 12 sheaves to the thrave.

THRASYBULUS, a renowned Athenian general and patriot, the deliverer of his country from the yoke of the 30 tyrants, lived about 294 B. C.*

THRASYMENUS LACUS, (*anc. geog.*) a lake of Etruria, near Perugia, and not far from the Tiber, *fa. 174*.
* See *Attica*.

THREAD, a small line made up of a number of fine hairs of any vegetable or animal substance, such as flax, cotton, or silk; from which thread takes its name of linen, cotton, or silk.

Thrace

Thread.

Thread *Nettle* THREAD. See NETTLE and URTICA.
 Dyeing THREAD black. Linen and cotton thread may be dyed of a durable and deep black by solution of iron in four beer, in which the linen is to be steeped for some time, and afterwards boiled in madder. See the article DYEING, Part III.

THREATENING LETTERS. Knowingly to send any letter without a name, or with a fictitious name, demanding money, or any other valuable thing, or threatening (without any demand) to kill or fire the house of any person, is made felony without benefit of clergy. And sending letters, threatening to accuse any person of a crime punishable with death, transportation, pillory, or other infamous punishment, with a view to extort from him any money or other valuable chattels, is punishable by statute 30 Geo. 2. c. 24, at the discretion of the court, with fine, imprisonment, pillory, whipping, or transportation for seven years.

THRIPS, a genus of insects, belonging to the order of hemiptera. The rostrum is obscure, or so small as to be scarce perceptible. The antennæ are filiform, and as long as the thorax. The body is slender, and of equal thickness in its whole length. The abdomen is reflexible, or bent upwards. The four wings are extended, incumbent upon the back of the insect, narrow in proportion to their length, and cross one another at some distance from their base. The tarsi of the feet are composed of only two articulations. There are five species. The largest is the juniperina, of a glossy black colour with yellowish antennæ; the wings and elytra are whitish, narrow, and furnished at the point with a few small hairs. The insects live under the bark of old trees, in flowers, and under the juniper-tree. In the same places are to be found their larvæ, which only differ from them by the want of wings and elytra; but it is difficult to observe these differences in such diminutive creatures, which look rather like moving atoms than any thing else.

THROAT, the anterior part of an animal, between the head and the shoulders, wherein is the gullet.

THRONE, a royal seat or chair of state, enriched with ornaments of architecture and sculpture, raised on one or more steps, and covered with a kind of canopy. Such are the thrones in the rooms of audience of kings and other sovereigns.

THRUSH, in ornithology. See TURDUS.

THRUSH, or *Aphthe*. See MEDICINE, n° 214.

THUANUS (Jacobus Augustus), youngest son of the president de Thou, was famous for the depth and erudition of his works. He was born in 1553; and having finished his studies and travels, was made president a-Mortier, and took possession thereof in 1595. He was employed in several important offices of state, and in reforming of the university of Paris; which he discharged with so much prudence, that he was esteemed the Cato of his age, and the ornament of France. He wrote the history of his own time in Latin, from the year 1543 to 1608, in 138 books; a work, both for subject and style, worthy of the ancients. He also left memoirs of his own life, besides poems; and died at Paris, 1617.

THUCYDIDES, a celebrated Greek historian, was born at Athens 475 B.C. He was the son of

Olorus, and grandson of Miltiades, who is thought to have been descended from Miltiades the famous Athenian general, and to have married the king of Thrace's daughter. He was educated in a manner suitable to his quality, that is, in the study of philosophy and eloquence. His master in the former was Anaxagoras, in the latter Antiphon; one, by his description in the eighth book of his History, for power of speech almost a miracle, and feared by the people on that account. Suidas and Photius relate, that when Herodotus recited his history in public, a fashion in use then and many ages after, Thucydides felt so great a sting of emulation, that it drew tears from him; inasmuch that Herodotus himself took notice of it, and congratulated his father on having a son who showed so wonderful an affection to the muses. Herodotus was then 29 years of age, Thucydides about 16.

When the Peloponnesian war began to break out, Thucydides conjectured truly, that it would prove an argument worthy of his labour; and it no sooner commenced than he began his history, pursuing the same, not in that perfect manner in which we see it now, but by way of commentary, and in writing down plain actions or passages thereof, as from time to time they fell out and came to his knowledge. We know nothing with certainty of Thucydides, but what he himself has delivered in his history. He was a lover of contemplation and retirement; yet did not decline the service of the state, and accepted accordingly of a command in the army. This, however, proved unfortunate to him; for while he resided in the Isle Thasus, it happened that Brasidas the Lacedæmonian besieged Amphipolis, a city belonging to the Athenians, about half a day's sail from Thasus. Thucydides being one of the strategæ, or of those who had authority to raise forces in those parts for the service of the commonwealth, the Athenian captain sent him to levy a power and hasten to his relief. Thucydides did so; but not arriving till too late, and when the city was already yielded up, he was afterwards banished, as if he had done this either through negligence or fear of the enemy; which, however, there was no just reason to suspect; for he put himself into the city Eion, and preserved it to the Athenians, with the refusal of Brasidas, who came down the next morning from Amphipolis and besieged it.

After his banishment, which happened in his 48th year, he lived in Scapte-Hyle, a city of Thrace, from whence he married a very wealthy wife; and he had large possessions and rich mines of gold, as he himself tells us in his fourth book. He was not however so affected with his disgrace, as to shut himself up from the world, and drag on, as many have done, a life embittered with spleen and disappointment; on the contrary, he went abroad, and was present at the actions of the rest of the war. This appears from his own words, in the fifth book of his History; where he says, that he was present at the actions of both parties, and by reason of his exile no less at those of the Peloponnesians than those of the Athenians. During this time he perfected his History, so far as is now to be seen. He was very nice and curious concerning a perfect insight into affairs; in order to obtain which he employed great sums of money in procuring authentic memorials, not only from the Athenians but the Lacedæmonians also, that out of his collec-

Thule
Thunder.

collections from both the great transactions of that time might be better and more impartially set forth.

At the end of 20 years, his sentence of banishment was revoked. Some authors affirm that he returned to Athens, and was treacherously killed in that city. But others assert that he died in Thrace, at the advanced age of 80 years, leaving his history unfinished. It is contained in eight books, and ends with the 21st year of the war of Peloponnesus. The most esteemed edition is that of Oxford in 1696, folio. Demosthenes set such a value on Thucydides's history, that he transcribed the whole several times with his own hand.

THULE, or THYLÆ, (anc. geog.) an island about the situation of which authors disagree. Strabo frankly owns that it lies in obscurity, and that what Pytheas of Marseilles says about it is not to be depended on. Pliny seems to have known a little more; namely, that it is the outmost or last of all the known islands, in which there are no nights at the summer-solstice: Ptolemy makes the longest day there 24 hours, and assigns it 63 degrees of north latitude. Stephanus allows but 20 for the longest day. From all which it appears evident to some, that the ancients could not mean Iceland, as is commonly thought, but either Stetland or Ferro, as agreeing tolerably well with the days and hours above-mentioned; though others are of opinion that Iceland is the Thule of the ancients. Agricola, in sailing round Britain, says, he had then a view of Thule, lying in snow and involved in winter; whereas Iceland lies at too great a distance to be seen in sailing round Britain. Nor is it certain whether they took it for some ordinary island, or for the great peninsula of Scandinavia; that is, Sweden and Norway, which very many authors formerly took for an island. Pliny, however, seems to have distinguished Norway from Thule; who places beyond it, at the distance of a day's sail, the Frozen Sea, called *Cronium* by some, and *Pigum* by Tacitus. All the knowledge either Greeks or Romans had of this island, Bochart supposes to have been derived from the Phœnicians. Antonius Diogenes, a very ancient author, who lived in the time of Alexander the Great, and who wrote concerning the island of Thule, professes he drew his tale or his story from the *Tabule Cyparißine* dug up at Tyre, when taken by Alexander, from the tomb of the Tyrian adventurers who sailed thither.

Southern THULE. See AMERICA, n° 21.

THUMB, in anatomy, one of the extremities of the hand.

THUMB-Cap, an island in the South-Sea, lies about seven leagues north-west of Lagoon-island; it is a low, woody island, of a circular form, and not much above a mile in compass. There was no appearance of inhabitants; the land was covered with verdure of many hues.

THUMMIM. See URIM.

THUNDER, the noise occasioned by the explosion of a flash of lightning echoed back from the inequalities on the surface of the earth, in like manner as the noise of a cannon is echoed, and in particular circumstances forms a rolling lengthened sound.

Although *thunder*, properly speaking, is only a mere sound capable of producing very little effect, yet

the word is generally supposed to include the phenomena of lightning also; and electrified clouds are by universal consent called *thunder-clouds*, and the explosions of many flashes of lightning proceeding from them are generally called *thunder-storms*. Though the phenomena of lightning, therefore, have been at great length explained and accounted for under the articles ELECTRICITY and LIGHTNING, and though the immediate cause of electrical explosions from clouds is explained under the article RAIN; yet the ultimate cause remains still to be shown, and properly belongs to the present article.

It is universally allowed, that the variation of the electricity in different parts of the atmosphere is the cause of thunder. Under the article ELECTRICITY, it has been shown why lightning explodes after the thunder-clouds are charged. Under the article LIGHTNING it is shown why that meteor puts on the various forms in which we see it, why it sometimes strikes houses or animals, and sometimes not, &c.; and under the article RAIN, why the atmosphere in some cases parts with the vapours which at other times it so obstinately retains. It remains, therefore, only to show why rains are sometimes attended with thunder, and sometimes not; which, to those who attentively peruse the articles above-mentioned, may be done in few words.

In this part of Great Britain, and for a considerable way along the eastern coast, although thunder may happen at any time of the year, yet the month of July is that in which it may almost certainly be expected. Its duration is of very uncertain continuance; sometimes only a few cracks will be heard at any particular place during the whole season; at others the storm will return at the interval of three or four days for a month, six weeks, or even longer; not that we have violent thunder in this country directly vertical in any one place so frequently in any year, but in many seasons it will be perceptible that thunder-clouds are formed in the neighbourhood even at these short intervals. Hence it appears, that during this particular period there must be some natural cause operating for the production of this phenomenon, which does not take place at other times. This cannot be the mere heat of the weather, for a great tract of hot weather is very often observed without any thunder being heard; and besides, though not common, it is sometimes heard in the winter also. As therefore the heat of the weather is common to the whole summer, whether there be thunder or not, we must look for the causes of it in those phenomena, whatever they are, which are peculiar to the months of July, August, and the beginning of September. Now it is generally observed, in the tract of country of which we now speak, that from the month of April an east or south-east wind generally takes place, and continues with little interruption till towards the end of June. At that time, sometimes sooner, and sometimes later, a westerly wind takes place; but as the causes producing the east wind are not removed, the latter opposes the west wind with its whole force. At the place of meeting, there is naturally a most vehement pressure of the atmosphere, and friction of its parts against one another; a calm ensues, and the vapours brought by both winds begin to collect and form dark clouds, which can have little motion

Thunder.

Thunder,
Thuringia

motion either way, because they are pressed almost equally on all sides. For the most part, however, the west wind prevails, and what little motion the clouds have is towards the east; whence the common remark in this country, that "thunder-clouds move against the wind." But this is by no means universally true: for if the west wind happens to be excited by any temporary cause before its natural period when it should take place, the east wind will very frequently get the better of it; and the clouds, even although thunder is produced, will move westward. Yet in either case the motion is so slow, that the most superficial observers cannot help taking notice of a considerable resistance in the atmosphere.

That when two streams of air are thus driven against each other, the space where they meet must become highly electrified, is as plain as that an electric globe must be excited when friction is applied. It is true, as the substances here to be excited are both electric *per se*, it may be objected, that no electricity could be produced; for we cannot excite one electric by rubbing it with another. Yet it is observed, that glass may be electrified by blowing strongly upon it, or by the explosion of cannon; and even when glass is strongly pressed upon glass, both pieces become electrified as soon as they are separated. When glass is rubbed upon glass, no attraction or repulsion can be perceived, nor is any sign of electricity observed on bodies brought near to it; yet a very bright electric light always appears on the glasses, and a phosphoreal smell is smelt; which shows, that though the electricity does not fly out through the air in the usual way, yet the fluid within the glass is agitated, and there is little reason to doubt that any conducting body inclosed within the substance of the glass would be electrified also. The vapours therefore, which are the conducting substances in the atmosphere, become immediately electrified in consequence of the pressure above-mentioned, and all the phenomena described under the various articles already referred to take place.

In like manner, by the struggle of two other winds as well as those of the east and west, may a thunder-storm be produced; but it is always necessary that the resistance of the air to the motion of the clouds should be very great, and nearly equal all round. For if the vapour should get off to a side, no thunder would take place; the electricity would then be carried off as fast as it was collected, and rain would only be the consequence, by reason of the electrified vapours parting with their latent heat, as is explained under the article RAIN. In fact, we very often observe that in the time of rain the clouds evidently move across the wind, and the nearer their motion is to a direct opposition, the heavier will the rain be; while on the other hand, if they move briskly before the wind, let the direction be what it will, the atmosphere soon clears up. But for a farther illustration of these matters, see the articles WEATHER, and WIND.

THURINGIA, a division of the circle of Upper Saxony in Germany. It is a fruitful track, abounding in corn, especially wheat; in black cattle, sheep, and horses; and in some places with vines and wood, and other valuable plants. It contains 47 towns, 14 boroughs, betwixt 700 and 800 villages, 300 noble estates, 7 superintendencies, and 5 under-consistories.

Thurloe
Thuya.

Thuringia, the country of the ancient Thuringi, or Catti, a branch of the Vandals, mentioned by Tacitus, was formerly a kingdom, afterwards a county, then a landgravate, and was governed by its own princes for many ages, till 1124, when it devolved to the marquis of Misnia, and, with that country, afterwards to the duke of Saxony. But the modern Thuringia is only a part of the ancient, nay, but a part of the ancient South Thuringia, which comprehends besides, a large share of the modern Franconia, Hesse, &c. On the extinction of the male line of the ancient landgraves in 1247, it came to the margraves of Meissen, ancestors to the present electoral family. The elector has no voice in the diet, on account of his share in the landgravate or circle of Thuringia.

THURLOE (John), an English statesman under Oliver Cromwel; was born at Abbots Roding in Essex in 1616, of which parish his father was rector; and was educated to the study of the law. In 1648 he was made receiver or clerk of the excise fines; and though his attachments were entirely on the side of the parliament, he declares himself totally unconcerned in all counsels relative to the death of the king: however, on that event, and on the establishment of the commonwealth, he was diverted from prosecuting his employments in the law, by engaging in public business. When Cromwel assumed the protectorship, he became secretary of state; in 1655, he had the care and charge both of foreign and inland postage committed to him by the protector; and was afterward sworn one of his privy-council, according to "The humble petition and advice." He was continued in the same capacities under Richard Cromwel, and until measures were taking for the restoration; when he made an offer of his services to that end, which however were not accepted. May 15th 1660, he was committed to the custody of the serjeant at arms on a charge of high-treason; but being soon released, he retired to Great Milton in Oxfordshire: and though he was afterward often solicited by Chas. II. to engage in the administration of public business, he thought proper to decline the offers. He died in 1668; and was a man of an amiable private character, who in the highest of his power exercised all possible moderation toward persons of every party. The most authentic testimony of his abilities is that vast collection of state-papers, 7 vols folio, now in the hands of the public; which place the affairs of Great Britain, and of Europe in general, during that remarkable period, in the clearest light.

THURSDAY, the fifth day of the Christian week, but the sixth of that of the Jews.

THUYA, the ARBOR VITÆ, a genus of the monodelphia order, belonging to the monoecia class of plants. The species are,

1. The occidentalis, or common arbor vitæ, grows naturally in Canada, Siberia, and other northern countries. In some of the English gardens a few of these trees are to be met with of a large size: it has a strong woody trunk, which rises to the height of 40 feet or more. The bark, while young, is smooth, and of a dark brown colour; but as the trees advance, the bark becomes cracked, and less smooth. The branches are produced irregularly on every side, standing almost horizontal, and the young slender shoots frequently hang downward, thinly garnished with leaves; so that when the

† See Elec-
tricity, no
17, 28, 96.

the trees are grown large, they make but an indifferent appearance. The young branches are flat, and their small leaves lie imbricated over each other like the scales of a fish; the flowers are produced from the side of the young branches pretty near to the foot-stalk; the male flowers grow in oblong catkins, and between these the female flowers are collected in form of cones. When the former have shed their farina, they soon after drop off; but the female flowers are succeeded by oblong cones, having obtuse smooth scales, containing one or two oblong seeds. The leaves of this tree have a rank oily scent when bruised.

2. The *orientalis*, or China arbor vitæ, grows naturally in the northern parts of China, where it rises to a considerable height; but this has not been long enough in Europe to have any trees of large size. The seeds of this sort were first sent to Paris by some of the missionaries; and there are some of the trees growing in the gardens of the curious there, which are more than 20 feet high. The branches of this sort grow closer together, and are much better adorned with leaves, which are of a brighter green colour, so make a much better appearance than the other, and being very hardy, it is esteemed preferable to most of the evergreen trees with small leaves, for ornament in gardens. The branches of this tree cross each other at right angles: the leaves are flat; but the single divisions of the leaves are slender, and the scales are smaller and lie closer over each other than those of the first sort. The cones are also much larger, and of a beautiful grey colour; their scales end in acute reflexed points.

These trees are propagated by seeds, layers, or cuttings.

THYMUS, *THYME*, a genus of the gymnospermia order, belonging to the didynamia class of plants. There are several species, all celebrated for their agreeable flavour, but so well known that no description is necessary. The whole plant is fragrant, and yields an essential oil that is very heating. An infusion of the leaves removes the headache occasioned by the debauch of the preceding evening. A general opinion prevails that the flesh of sheep that feed upon aromatic plants, particularly upon thyme, is much superior in flavour to common mutton: but the ingenious author of the account of the Sheep-walks in Spain (*Gent. Mag.* 1764.) considers this as a vulgar error. He says sheep are not fond of aromatic plants; that they will carefully push aside the thyme to get at the grass growing beneath it; and that they never touch it unless when walking apace, and then they will catch at any thing. — The attachment of bees to this and other aromatic plants is well known. In the experiments made at Upsal, sheep and goats were observed to eat it, and swine to refuse it.

THYMUS, in anatomy. See **ANATOMY**, n° 379.

THYRSUS, in antiquity, the sceptre which the poets put into the hand of Bacchus, and wherewith they furnished the menades in their Bacchanalia.

THYRSUS, in botany, a mode of flowering resembling the cone of a pine. It is, says Linnaeus, a pinnule contracted into an oval or egg-shaped form. The lower foot-stalks, which are longer, extend horizontally, whilst the upper ones are shorter and mount vertically. Lilac and butter-burr furnish examples.

TIARA, an ornament or habit wherewith the ancient Persians covered their head; and with which the Armenians and kings of Pontus are represented on medals; these last, because they were descended from the Persians. Latin authors call it indifferently *tiara* and *cidaris*. Strabo says, the tiara was in form of a tower; and the scholiast on Aristophanes's comedy, *AXES*, act. 1. scene 2. affirms, that it was adorned with peacock's feathers.

The kings of Persia alone had the right of wearing the tiara straight and erect; the priests and great lords wore it depressed, or turned down on the fore-side. Xenophon in his *Cyropædia* says, that the tiara was sometimes encompassed with the diadem, at least in ceremonies; and had frequently the figure of a half-moon embroidered on it: others are of opinion, that the diadem was in figure of a moon, and that it was hence the tiara was called *lunata*: lastly, others think that the tiara itself was sometimes in form of a half-moon. In fact, it appears that there were different forms of tiaras; and Pachelius *De coronis*, distinguishes no less than five different kinds.

TIARA is also the name of the pope's triple crown. The tiara and keys are the badges of the papal dignity; the tiara of his civil rank, and the keys of his jurisdiction: for as soon as the pope is dead, his arms are represented with the tiara alone, without the keys. The ancient tiara was a round high cap. John XXIII. first encompassed it with a crown. Boniface VIII. added a second crown; and Benedict XII. a third.

TIBER, a great river of Italy, which runs through the pope's territories, passing by Perugia and Orvieto; and having visited Rome, falls into Tuscan sea at Ostia, sixteen miles below that city.

TIBERIAS, (anc. geog.) the last town of Galilee, situated on the south side of the lake Tiberias; built by Herod the tetrarch, and called *Tiberias* in honour of the emperor Tiberius; distant 30 stadia from Hippus, 60 from Gadara, and 120 from Scythopolis: whence it appears to have been at no great distance from where the Jordan runs out of the lake. It is a number of times mentioned by John the Evangelist. Pliny places it on the west extremity of the lake, commending the salubrity of its hot waters. Jerome says, the ancient name was *Chinnereth*; which, if true, will account for the name of the lake.

TIBULLUS (Aulus Albius), a Roman knight, and a celebrated Latin poet, was born at Rome 43 B. C. He was the friend of Horace, Ovid, Macer, and other great men in the reign of Augustus. He accompanied Messala Corvinus in his expedition against the island of Coreyra: but falling sick, and being unable to support the fatigues of war on account of the weakness of his constitution, he quitted the profession of arms, and returned to Rome, where he died before the year 17; when Ovid showed his grief for his death by writing a fine elegy upon him. Tibullus wrote four books of elegies, which are still extant: they are written in a tender and agreeable style, and in a very elegant Latin. Muret and Joseph Scaliger have written learned and curious commentaries on the works of this poet. The best edition of Tibullus is that of Janus Bronchhius, published at

Tibur
||
Tide.

Amsterdam in 1708, in one volume quarto. We have an English poetical version of them by Mr Grainger.

TIBUR, (anc. geog.) a town of Latium, pleasantly situated on the Anio. Here Horace had his villa and house; and here he wished to end his days. Here Adrian built an extraordinary villa called *Tibur-tina*, inscribed with the names of the provinces and of the most considerable places, (Spartian; near which Zenobia had a house called *Zenobia*, (Trebellius, Pollio). Hither Augustus often retreated on account of its salubrity, (Suetonius): for which it is greatly commended, (Martial). Anciently, when the Romans had far extended their territory, it was the utmost place of banishment, (Ovid). It had a temple of Hercules; and therefore called *Herculeum*. In the temple was a library, (A. Gellius). Now *Tivoli* in the Campagna di Roma on the Teverone.

TICINUM, (anc. geog.) a town of Infubria, built by the Gauls; situated on the river Ticinus near its confluence with the river Po: a municipium, famous under the Cæsars. Now *Pavia* in the Milan, from its name *Pabia* or *Papia* in the middle age.

TICINUS, (anc. geog.) a river in Infubria, rising in mount Adula, traversing the Lacus Verbanus southwards, and falling into the Po near Ticinum. Between this river and the Po Hannibal gained his first victory over the Romans under P. Scipio. The general himself escaped with the utmost difficulty, and that by the bravery of his son the first Scipio Africanus. Now the *Tesino*, rising in mount Godard, running south through the Lago Maggiore and Milan, by Pavia, into the Po.

TICKELL (Thomas), an excellent English poet, was the son of a clergyman who enjoyed a considerable preferment in the north of England; but we have no account where or when he was born. He was educated at Queen's college, Oxford, of which he was made-fellow; and while he continued at that university, he addressed to Mr Addison a complimentary copy of verses on his Opera of Rosamond, which introduced him to an acquaintance with that gentleman, who discovering his merit, became his sincere friend. On Mr Addison's being made secretary of state, he appointed Mr Tickell his under-secretary; and on his being obliged to resign that office on account of his ill health, he recommended him so effectually to Mr Craggs his successor, that he was continued in his post till that gentleman's death. In 1724 Mr Tickell was appointed secretary to the lords justices in Ireland, and enjoyed that place as long as he lived. He wrote some poems, which, when separately published, met with a favourable reception, and passed through several editions: they are now printed in the second volume of The Minor Poets. After Mr Addison's death Mr Tickell had the care of the edition of his works printed in 4 vols 4to; to which he prefixed an account of Mr Addison's life, and a poem on his death. Mr Tickell died in the year 1740.

TIDES. See ASTRONOMY, n° 161. *et seq.*

TIDE-WAITERS, or *Tidesmen*, are inferior officers belonging to the custom-house, whose employment is to watch or attend upon ships until the customs be paid: they get this name from their going on board ships on their arrival in the mouth of the Thames or other ports, and so come up with the tide.

Tiend
||
Tillandfia.

TIEND, in Scots law. See LAW, n° clxxi.

TIERCE, or **TEIRCE**, a measure of liquid things, as wine, oil, &c. containing the third part of a pipe, or 42 gallons.

TIERCED, in heraldry, denotes the shield to be divided by any part of the partition-lines, as party, coupé, tranchy, or tailly, into three equal parts of different colours or metals.

TIGER, in zoology. See FELIS.

TIGRIS, a river of Asia, which has its source near that of the Euphrates in the mountain Tchildir in Turkomania: afterwards it separates Diarbeck from Erzerum, and Khufistan from Irac-Arabi; and uniting with the Euphrates at Gorno, it falls into the gulph of Buzarah, under the name of *Schat el-Arab*. This river passes by Diarbekar, Geziral, Mouful, Bagdad, Gorno, and Buzarah.

TILBURY, a fortress in the county of Essex, seated on the river Thames, opposite to Gravesend in Kent.

TILIA, the LIME OF LINDENTREE; a genus of the monogynia order, belonging to the polyandria class of plants. The most remarkable species is the *Europæa*, or common lime-tree, a native of Britain and other northern countries of Europe. The leaves are heart-shaped, with the apex produced, and serrated on the edges; the flowers grow in a thin umbel, from three to nine together, of a whitish colour and a fragrant smell; very grateful to bees. The wood is light, smooth, and of a spongy texture, used for making lalls and tables for shoemakers, &c. Ropes and bandages are made of the bark, and mats and rustic garments of the inner rind, in Carniola and some other countries.—The lime-tree contains a gummy juice, which being repeatedly boiled and clarified, produces a substance like sugar.

TILLANDSIA, the large barren WILD PINE of the West Indies; a genus of the monogynia order, belonging to the hexandria class of plants. It is called *Caragatua* by Father Plumier, and is a parasitic plant, and ought perhaps, in strict propriety, to be denominated an *aquatic*: for although it is suspended in the air among the branches of lofty trees, to whose boughs it is fastened by its numerous roots; yet it is not indebted to those boughs, like the mistletoe and other parasitic plants, for nourishment, but merely for support; provident nature having, in a very extraordinary manner, supplied this with other means to preserve its existence: for the leaves, which much resemble those of the pine-apple, but are larger, surround this plant in a circular manner; each leaf being terminated near the stalk with a hollow bucket, which contains about half a pint of water. It is by these numerous small reservoirs of water, that the roots, as well as every other part of this plant, are supplied with nourishment, without the help of any earth. The flourishing condition of this plant, as well as the great growth of fig-trees, upon barren rocks, shows that water is of greater use to vegetation than earth.

One contrivance of nature in this vegetable, says Dr Sloane, is truly admirable. The seed is crowned with many long, downy threads, not only that it may be carried everywhere by the wind; but that by those threads, when driven through the boughs, it may be held fast, and stick to the arms and prominent parts of the

Tillotmont
|
Tillotson.

the barks of trees. So soon as it sprouts or germinates, although it be on the under-part of a bough, its leaves and stalks rise perpendicular or erect; if they assumed any other direction, the cistern or reservoir just mentioned, made of the hollow leaves, could not hold water, which is necessary to the life and nourishment of the plant. In scarcity of water this reservoir is useful, not to the plant only, but to men, and even to birds and all sorts of insects, which come thither in troops, and seldom go away without refreshment.

To the same purpose, Dampier, in his voyage to Campeachy, relates, "that the wild pine has leaves that will hold a pint and a half or quart of rain-water, which refreshes the leaves and nourishes the roots. When we find these pines we stick our knives into the leaves, just above the root; and the water gushing out, we catch it in our hats, as I myself have frequently done, to my great relief."

TILLEMONT. See NAIN.

TILLER of a SHIP, a strong piece of wood fastened in the head of the rudder, and in small ships and boats called the *helm*.

TILLOTSON (John), a celebrated archbishop of Canterbury, was the son of Robert Tillotson of Sowerby, in the parish of Halifax in Yorkshire, clothier; and was born there in the year 1630. He studied in Clare-hall, Cambridge; and in 1656 left this college, in order to become tutor to the son of Edmund Prideaux, Esq; of Ford-abbey in Devonshire. He was afterwards curate to Dr Hacket vicar of Cheshunt, in Hertfordshire. In 1663, he was presented by Sir Thomas Barnardiston to the rectory of Ketton or Kedington in the county of Suffolk; but was the next year chosen preacher to Lincoln's Inn, when he procured Ketton to be bestowed on his curate. He was greatly admired in London for his sermons; and the same year was appointed Tuesday-lecturer at St Lawrence's church, London, where his lectures were frequented by all the divines of the city and many persons of quality and distinction. In 1666, he took the degree of doctor of divinity at Cambridge; in 1669, was made prebendary of Canterbury; in 1672, was admitted dean of that cathedral; and three years after, was made a prebendary of St Paul's cathedral, London. In 1679, he became acquainted with Charles earl of Shrewsbury, whom he converted from Popery; and the next year refused to sign the clergy of London's address of thanks to king Charles II. for not agreeing to the bill of exclusion of the duke of York. In 1683, he visited the unhappy lord Russell when under condemnation; and attended him in his last moments on the scaffold. In 1689, he was installed dean of St Paul's; made clerk of the closet to king William and queen Mary; and appointed one of the commissioners to prepare matters to be laid before the convocation, in order to a comprehension of all Protestants, as well dissenters as churchmen; but this attempt was frustrated by the zeal of those members of that body, that refused to admit of any alteration in things confessedly indifferent. In 1691, Dr Tillotson was, notwithstanding the warmest remonstrances and intreaties on his part, consecrated archbishop of Canterbury, and four days after was sworn one of the privy-council; their majesties always reposing an entire confidence in his prudence, moderation, and integrity. In 1694, he

was seized with a dead palsy, of which he died in the 65th year of his age. He was interred in the church of St Lawrence Jury, London, where a neat monument is erected to his memory. This learned and pious divine, while living, was greatly inveighed against by the enemies of the revolution. After his death there was found a bundle of bitter libels which had been published against him, on which he had written with his own hand, "I forgive the authors of these books, and pray God that he may also forgive them." It is remarkable, that while this truly great man was in a private station, he always laid aside two-tenths of his income for charitable uses. One volume in folio of Dr Tillotson's sermons was published in his life-time, and corrected by his own hand: these Barbeyrac translated into French. Those which came abroad after his death, from his chaplain Dr Barker, made two vols in folio, the copy of which was sold for 2500 l. and this was the only legacy he left to his family, his extensive charity having consumed his yearly revenues as constantly as they came to his hands. However, king William gave two grants to his widow; the first of which was an annuity of 400 l. during the term of her natural life, and the second of 200 l. as an addition to the former annuity. Dr Tillotson wrote some other works besides his Sermons; and also published Dr Barrow's works, and Dr Wilkins's Treatise of the Principles and Duties of Natural Religion, and a volume of that divine's Sermons.

TIMÆUS, a Greek historian, the son of Andronicus, who was eminent for his riches and excellent qualities, was born at Tauromenium in Sicily, and flourished in the time of Agathocles. He wrote several books, and among the rest an history of his own country; but they are all lost.

TIMÆUS, a famous Pythagorean philosopher, was born at Locres in Italy, and lived before Plato. There is still extant a small treatise of his on the Nature and Soul of the World, written in the Doric dialect. This treatise, which is to be found in the works of Plato, furnished that great philosopher with the subject of his treatise intitled *Timæus*.

TIMBER, a name for all kinds of felled and seasoned woods. See TREES and WOOD.

TIMBERS, the ribs of a ship, or the incurvated pieces of wood, branching outward from the keel in a vertical direction, so as to give strength, figure, and solidity to the whole fabric. It has been observed in the article *Naval ARCHITECTURE*, that one timber is composed of several pieces united into one frame, which is accordingly called a *frame of timbers* by the artificers. These different pieces are exhibited in Plate CCLXVI. fig. 3. by U, V, and W; the head of the lower piece, called the *floor-timber*, being cut square, to join the heel of the next above it. To support the connection of the timber in that place, another assemblage of pieces are formed, and joined in the same manner; so that when both the sets are fastened together, the joinings in one set will be nearly opposite to the middle of the pieces in the other. Hence it is evident, that the mould which serves for the lowest piece will conform to the under part of the corresponding piece above it; and thus the mould appropriated to every division of a timber will determine or answer to the figure of the next adjoining thereto.

Timæus
|
Timbers.

Time.

—The timbers, whose areas or planes are perpendicular to the keel, are called *square-timbers*; and those which are placed obliquely on the keel, as at the extremities of a ship, are called *cant-timbers*. The foremost of those pieces on the ship's bow are called the *knuckle-timbers*; and the hindmost on the quarter are called the *fashion-pieces*.—The outlines, or bends of the principal timbers of the ship, are geometrically delineated in the plane of projection, *ibid.* fig. 4. as also in Plate CLIX. fig. 2. and Plate CCLXXVII. fig. 2.; and their particular stations in the ship's length are represented in the horizontal plane, and that of the elevation, Plate CCLXVI. fig. 1, 2. In order to give a more comprehensive idea of their figures and dimensions, we have exhibited a perspective view of the carcase of a small vessel Plate CCLXXXVI. fig. 1. confining only of the keel A, the stern-post B, the stem C, the transoms KLM, and the ribbands FF.

TIME, a succession of phenomena in the universe, or a mode of duration marked by certain periods or measures, chiefly by the motion and revolution of the sun. See ASTRONOMY.

The general idea which time gives in every thing to which it is applied, is that of limited duration. Thus we cannot say of the Deity, that he exists in time; because eternity, which he inhabits, is absolutely uniform, neither admitting limitation nor succession.

TIME, in music, is that which measures the duration of sounds; and is marked by emphatic or accented notes, which are heard at equal distances, or by the regular returns of cadences.

A succession of sounds, says Rousseau, however happily it may be conducted in its procedure, in its transitions from low to high, or from high to low, will produce nothing, if we may speak so, but indeterminate effects. It is the relative and proportionate duration of these very sounds that fixes the genuine character of any music, and gives it its full energy. Time is the soul of melody: airs, whose movements are slow, naturally deject our spirits, and inspire sadness; but those which proceed with cheerfulness and vivacity, whose cadences are regular and properly marked, excite us to joy, and scarce can the feet restrain themselves from dancing. Remove measure, destroy the proportions of duration between sounds, and the same airs which those proportions rendered agreeable to you, will remain without charms and without force, will, in short, become incapable of pleasing or interesting. Time, on the contrary, has its own intrinsic power; it depends on itself alone, and can subsist without diversity of sounds. Of this the drum presents us with an example; rude indeed, and extremely inadequate, because in it the sounds cannot be supported.

Time in music is considered, either with respect to the general movement of an air, and in this sense it is said to be *swift or slow*; or it is considered with respect to the aliquot parts of every bar; these parts are marked by motions of the hand or foot, and in a particular sense are called *times*: or, in short, it is considered with respect to the proper value of each particular note in duration.

In his Musical Dictionary, at the word *Rhythme*, Rousseau has sufficiently treated concerning the time of music among the Greeks. Such readers as wish to examine the rhythmos of the ancients more curiously,

Time.

may derive considerable advantage from reading Cicero's treatise *De Oratore*, and Burney's dissertation prefixed to his history. We are more particularly concerned in the *time of modern music*.

Those musicians who may be called *ancient moderns*, only recognize two different species of measures or times; one containing three equal divisions of time, which they called *perfect measure*; the other comprehending two, which they termed *imperfect measure*; and they denominated the signs which they added to the cleft, *times, modes, or prolations*, to fix the character of the bars, whether of the one or the other kind. These signs did not, as at present, serve for that use alone, but they likewise fixed the relative value of notes; as may be seen at the words *Mode and Prolation* in Rousseau's Musical Dictionary, with respect to the maximum or large, the long, the semibreve. With respect to the breve, the manner of dividing it was what they more precisely called *time*; and that time was *perfect* or *imperfect*.

When the time was *perfect*, the breve or square was equivalent to three semibreves; and this they signified by a full circle, sometimes with lines drawn through it and sometimes not, sometimes likewise it was marked thus 3.

When the time was *imperfect*, the breve was only equivalent to two semibreves; and this was marked by a semicircle or C. Sometimes this C was inverted; and this signified that the value or duration of each particular note was diminished by one half. We at present express the same thing by intersecting C with a line. Sometimes the quantity of a bar, signified by the intersected C, where the notes only are protracted to half their value, divided into what they called *minor times*; and that which was marked by the C without a line, where the notes occupied their full duration, into *major times*, in which the bar was generally divided into four equal parts or times.

We have exactly retained the triple time of the ancients, as well as the double, which we call *common time*; but, by an unaccountable caprice, we have hardly retained any thing in their manner of dividing notes except by duplicates, though their division into three equal parts is often no less necessary to us than to them; so that to divide a bar into three equal parts, or a time in the same manner, we are at a loss for characters of expression, and scarcely can we tell how to supply them. We must have recourse to the figure 3, or to other expedients of the same kind; which demonstrate how inadequate our musical characters are to answer their proper purposes. See TABLES in the *Musical Dictionary*.

To ancient music we had added a combination of time, by which the bar, instead of two, is divided by four, equal parts or times; but as they may always be reduced to bars containing only two, it may be said, that in reality we have only two or three times as the aliquot parts of all our different bars.

The value of times is as numerous and different as the diversities in the quantity of bars and the modifications of movement. But when the bar and the movement are once fixed, all the bars should be perfectly equal, and all the times contained in each bar perfectly equivalent one to another. Now, to render this equality sensible, every bar is struck, and every time distinguished, by a motion of the hand or foot; and by these motions

Time.

motions the different values of notes are exactly regulated, according to the genius and character of the bar. It is a surprising phenomenon to observe with how much precision, by the assistance of a little habit and practice, initiates may be brought to follow and distinguish the times, with an equality so perfect, that no pendulum can vibrate more justly than the hand or foot of a good musician, and that even the internal perception of this equality is sufficient to conduct them and to answer with accuracy every purpose of sensible motion; so that, in a concert, every performer plays or sings the bar with the utmost exactitude, without hearing the time distinguished by any other, or distinguishing it himself any other ways than by the succession of his own ideas.

Of the different times included in a bar, though all are equal, yet there are some more strongly and sensibly marked than others. This distinction is expressed in execution by emphatic or accented notes, and by such as are unaccented or common. The time which is thus more sensibly distinguished is called the *perfect time*; that which is more feebly distinguished, or which is occupied by unaccented notes, is called the *imperfect time*. (See MUSIC, art. 174.) The perfect is the first of every bar, consisting of two times; it is the first and third of such bars as include three or four times. The second time is always imperfect in every bar, and it is the same case with the fourth in bars containing four times.

If every time be subdivided into two other equal parts, which may likewise be called *isochronic* or *hemichronic times*, for the first part of this subdivision you will likewise have a perfect time, and for the second an imperfect; and there is no part of any time which may not, according to Rousseau, be subdivided in the same manner.

Here, however, we must dissent; and for this plain reason, that notes may be so minutely subdivided, as by the shortness of their duration to be rendered incapable of emphasis; and we should be glad to know how this author, either with his hand, his foot, or this thought, could distinguish the perfect and imperfect times of a demi-semiquaver.

Every note which begins in the imperfect and ends in the perfect time, is an *antichronic* note; and as it violates and shocks in some measure the order of the bar, its commencement in the middle of one time, and its continuation to another, is called *syncopation*.

These observations are necessary to such as would learn how they may employ dissonances with success. For every dissonance properly introduced, ought to be prepared in the imperfect, and struck in the perfect time: except, however, in successions of cadences avoided, where this rule, though applicable to the first dissonance, is not equally so to those which succeed it. See DISCORD and PREPARATION.

TIME-KEEPERS, or Instruments for measuring Time. See CLOCK, DIAL, &c.

TIME KEEPERS for finding the Longitude. Gemma Frisius seems to have been the first who suggested the method of finding the longitude at sea by means of watches or time-keepers; which machines were then, as he says, but lately invented. After him Metivus, and some others, attempted it; but the state of watch-making was then too imperfect for this purpose. The

Time.

dispute between Hooke and Huygens, concerning the invention and application of the pendulum-spring to watches, was long and violent: each of them claiming this curious and most useful invention, and representing the other as a pirate. It is probable that their claims were each of them just; nor is this the only instance in which different persons have made the same discovery, nearly about the same time. Hooke and Huygens, each of them, on making this discovery, applied it to the purpose of discovering the longitude at sea. Some disputes, however, between the former of those gentlemen and the English ministry at that time, prevented the making any experiments with watches constructed by him; but many experiments were made with watches constructed by Mr Huygens, from which it appeared that those watches were of no real use at sea for this purpose. Dr Hooke never, as far as we know, made a full discovery of his inventions of this kind; but many hints are dropped in different parts of the Philosophical Transactions, his Philosophical Collections, and Culerian Lectures; of which later mechanics have undoubted availed themselves.

In 1714, an act passed for giving 20,000*l.* to that person who should first discover a method by which a ship might sail from England to any port in the West Indies, without having committed an error of 30' in her longitude, on arriving at the said port. The first who turned his thoughts this way, in consequence of this public encouragement, was Henry Sully, an Englishman, but who had left England before the passing of this act: for in 1714 he printed, at Vienna, a small tract on the subject of watch-making; and soon after he removed from thence and settled at Paris, where he spent the remainder of his life in improving time-keepers for the discovery of the longitude. In 1716 he presented a watch of his own making to the Royal Academy of Sciences, which was much approved. It is particularly said, that he had greatly diminished the friction; and that what he had not taken entirely away, he had by a very singular address rendered uniform. He went to Bourdeaux in 1726, for the convenience of trying his watches, and died there in 1728. The greater part of what is yet known of watch-making in France is principally to be attributed to him; for the famous Julien le Roy was his pupil, and owed most of his inventions to him, which he afterwards perfected and executed; and this gentleman, his son, and M. Berthoud, are the only persons in France who have turned their thoughts this way since the time of Sully. Several watches made by the two latter artists have been tried at sea at the expense of the king of France, and very voluminous accounts of these trials have been published with great pomp; but the facts which are there related are so very few, and those few enveloped in such a volume of words, vague and indeterminate in their meaning, that it is scarcely possible to discover from thence what these watches are capable of performing.

M. Berthoud, in a pretty bulky pamphlet in 4to, has with great labour collected together a few of the principal facts which resulted from the three last trials that were made of two time-keepers constructed by M. Le Roy, marked *A* and *S*; and of two of his own construction, denominated *N° 6.* and *N° 8.* which are as follow:

June

Time.

June 8th, 1768, being then at Havre de Grace, M. Le Roy's time-keeper *A* lost $1^{\circ} \frac{1}{2}$ a-day on mean time; and *S* gained 4° a-day. At the island of Miquelon, on the coasts of Newfoundland, *A* was losing at the rate of $0^{\circ} \frac{3}{4}$ a-day, and *S* gaining about 10° a-day on mean time. At Cadiz *S* gained on different days between the 16th and 30th of September $1^{\circ} \frac{1}{2}$, $1^{\circ} \frac{1}{4}$, 3° , $2^{\circ} \frac{1}{2}$, $3^{\circ} \frac{3}{4}$, $2^{\circ} \frac{1}{2}$ and $6^{\circ} \frac{1}{2}$ a-day on mean time; and *A* gained on the same day, respectively, 2° , $2^{\circ} \frac{1}{2}$, $3^{\circ} \frac{1}{2}$, $2^{\circ} \frac{1}{2}$, $5^{\circ} \frac{3}{4}$, $4^{\circ} \frac{1}{2}$, and $14^{\circ} \frac{1}{2}$ a-day. *A* gained on mean time, at Brest, from the 4th of November to the 7th, at the rate of $7^{\circ} \frac{1}{2}$ in 24 hours, and *S* at the rate of $5^{\circ} \frac{1}{5}$.

In November 1768, the time-keepers, No 6. and No 8. made by M. Berthoud, were put to the trial in a voyage conducted by M. Fleurieu.

| | No 8 lost per day. | No 6 lost per day. |
|------------------------------------------|-----------------------|-----------------------|
| Nov. 14th to Dec. 7th, at Rochford, | 4" 12 | 6" 33 |

| Nov. 1st to the 13th, at the Île of Aix, | 18 60 | 25 10 |

In the month of October 1771, two watches made by M. Le Roy, marked *A* and *S*, and M. Berthoud's, No 8. were again sent out on trial under Mess. Verdun, Borda, and Pingre. *A* was the same watch which had been tried before by the Marquis de Courtauvau and M. Cassini; but that marked *S* was a new one. They had also with them a small watch made by M. Le Roy, which, on account of its size and form, they called *La petite ronde*; but this did not answer at all. The performances of the other three were as follow:

| | No 8. | Watch A. | Watch S. |
|---------------------------------------|-------------|------------|-------------|
| At Brest, Oct. 10th to 26th, 1771, | Gain. 1" 39 | Lost 2" 14 | Gain. 1" 48 |

| Brest, 10th to 17th October, | Do. 0 04 | — | Do. 8 07 |

On the 17th of March the ship struck on the Wil-

lington Rock, which lies off the island of Antigua; and the thermometer of compensation for heat and cold of the watch *A* was broken by the shock, and the watch put entirely out of order. This accident was the cause of their putting back to Port Royal.

From this account it would appear, that M. Berthoud's time-keepers greatly exceed those of M. Le Roy: but it ought perhaps to be observed, that this (No 8.) is the only one of his making which has performed so well; and even this, on the former trial, did not go with any very great degree of regularity.

About the year 1726, Mr John Harrison, whose name is now so well known on account of his time-keepers, began to apply himself to the construction of them: and in the year 1736, one of them was tried on board his Majesty's ships, in a voyage to and from Lisbon; in which trial it gave so much satisfaction, that he received public encouragement to proceed, and began to entertain hopes of obtaining the reward offered by the act of the 12th of Queen Anne; in order to which, he made three other time-keepers, every one of which was more accurate, and better adapted to the purpose of measuring time truly at sea, than the former. The second of these was finished in 1739; and during the next ten years, its going was so much admired by the ingenious men of those times, that the annual prize-medal, distributed by the Royal Society, for improvements in experimental philosophy, was given to Mr Harrison on St Andrew's day, 1749. Mr Harrison did not finish his third machine until the year 1758; having then a fourth in considerable forwardness, and which he finished in October 1761: this proved so much to his satisfaction, that he wrote immediately to the commissioners of the board of longitude, informing them that he was then ready to make the ultimate trial prescribed by the above-mentioned act. Accordingly Mr William Harrison, son of the inventor, embarked on board his Majesty's ship *Deptford*, in November 1761, with this fourth time-keeper, on a voyage for Jamaica; and the longitude of the island, as shown by the time-keeper on his arrival there, differed but one minute and a quarter of the equator from the true longitude deduced from astronomical observations. The time-keeper also pointed out the longitudes of the several places which they saw in the course of the voyage, in a very exact manner. Mr Harrison junior returned to England with the time-keeper, in the latter end of March 1762, and found that it had erred in the whole, from its setting out to its return to England, no more than $1^{\circ} 54'' \frac{1}{2}$ in time, or $28 \frac{1}{2}$ minutes of longitude.

Mr Harrison now claimed the whole reward of 20,000*l.* offered by the act of the 12th of Queen Anne (1714); but some doubts arising in the minds of the commissioners concerning the true situation of the island of Jamaica, the manner in which the time at that place had been found, as well as at Portsmouth; and it being further suggested by some, that although the time-keeper happened to be right at these two times, namely when at Jamaica and on its return to England, it was by no means a proof that it had been always so in the intermediate times, another trial was proposed in a voyage to the island of Barbadoes, in which precautions were taken to obviate as many of those objections as possible. Accordingly, the commissioners having

Time.

Time. ving previously sent out proper persons to make astronomical observations at that island, which, when compared with other corresponding ones made in England, would determine beyond a doubt its true situation; Mr William Harrison again set out with his father's time-keeper, in the latter end of the month of March 1764, the watch having been compared with equal altitudes before he set out at Portsmouth; and arrived at Barbadoes about the middle of May: where, on comparing it again with equal altitudes of the sun, it was found to show the difference of longitude between Portsmouth and Barbadoes $3^{\circ} 55' 3''$. The true difference of longitude between these places, resulting from astronomical observations, is $3^{\circ} 54' 26''$: consequently the error of the watch was $43''$, or $10' 45''$ of longitude. The watch gained at the rate of $2''$, 58 a-day on mean time, from February 29th to March 21st, at Portsmouth; and lost at the rate of $2''$, 8 a-day, from May 14th to May 17th, at Barbadoes.

In consequence of this and the former trials, Mr Harrison received a moiety of the reward offered by the act of the 12th of Queen Anne, on his explaining the principles by which his time-keeper was constructed, and delivering it, as well as the former three, up to the commissioners of the longitude for the use of the public. He was also promised the other moiety of the reward, when other time-keepers were made on the same principles, either by himself or others, which performed equally well with that which he had last made. This last time-keeper was also sent down to the royal observatory at Greenwich, to be tried there under the direction of the Rev. Mr Maskelyne, his Majesty's astronomer royal. It did not appear, however, that during the time of this trial the watch went with the regularity that was expected; nor indeed with any thing near the regularity that it must actually have gone with during the course of the two voyages that had been made with it; which surprised many, and conveyed no favourable impression of the general utility of this method of discovering the longitude at sea; as it gave reasons for apprehending that the performance, even of the same watch, was not at all times equal; and consequently that little certainty could be expected in the performance of different ones. Moreover, the watch was now found to go faster than it did during its voyage to and from Barbadoes, by about 18 or 19 seconds in 24 hours: but this circumstance was accounted for by Mr Harrison, in a publication intitled, *Remarks on a Pamphlet lately published by the Rev. Mr Maskelyne*; where he tells us, that not expecting the watch would be required of him so soon as it was, he had altered the rate of its going, by trying some experiments which he had not time to finish before he was ordered to deliver the watch up to the board. It is possible that the watch might be disordered by these experiments, and that disorder be the cause of its subsequent irregularity.

Soon after this trial, the commissioners of longitude agreed with Mr Kendall, one of the watchmakers appointed by them to receive Mr Harrison's discoveries, to make another watch on the very same construction with this, in order to determine whether other watchmakers could make them from the account which Mr Harrison had given, as well as himself. The event proved the affirmative: for the watch produced by Mr

Kendall, in consequence of this agreement, went considerably better than that which had been made by Mr Harrison himself: and indeed better than any which have been made since on other principles, this only excepted which is the subject of the account before us.

This watch, made by Mr Kendall on Mr Harrison's construction, was sent out in the second voyage which Captain Cook made towards the South Pole, and round the world, in the years 1772, 1773, 1774, and 1775, to be tried under the care of Mr Wales, who was employed by the board of longitude for that purpose: and it appears from his account, that this watch was losing at the rate of $\frac{1}{2}$ of a second a-day, from March the 24th to April 25th 1772, at the royal observatory at Greenwich. August 1st 1772, at the island of Madeira, latitude $32^{\circ} \frac{1}{2}$ N. longitude 17° W. it lost at the rate of $1''$, 77 a-day on mean time. At the Cape of Good Hope, latitude $33^{\circ} \frac{1}{2}$ S. longitude 18° E. it gained at the rate of $1''$, 2 a-day on mean time, from November 2d to the 14th, 1772; and the greatest variation between the rates of its going on any two days was $5''$, 4. At Dusky Bay, in New Zealand, latitude $45^{\circ} \frac{1}{2}$ S. longitude 166° E. the watch gained at the rate of $6''$, 7 a-day, from the 6th of April to the 25th, 1773, and its greatest variation was $3''$, 6 from any one day to any other in that time. The watch gave the longitude of the island of Madeira $17^{\circ} 6' \frac{1}{2}$ W. which, for aught that is yet known to the contrary, is the exact longitude of that place. It made the longitude of the Cape of Good Hope $18^{\circ} 12' \frac{1}{2}$ E. which is about $11'$ short of the truth; and the longitude of Dusky Bay, in New Zealand, $163^{\circ} 47' \frac{1}{2}$ E. or too little by about $2^{\circ} 15' \frac{1}{2}$. But we ought, perhaps, with the person who had this watch then under his care, to observe, that in the compass of these 13 months the watch had passed through all climates, from the latitude of $51^{\circ} \frac{1}{2}$ N. to 67° S. and over a space nearly equal to the whole equatorial circumference of the earth. The only defect which appears to have been in this watch is, that its rate of going was continually accelerated; but in the three years and a half that it was under this trial, it never amounted to $14'' \frac{1}{2}$ a-day; for on its return to Greenwich, in the month of August 1775, it gained only $13''$ a-day; and its greatest rate during the voyage was at Fayal, one of the western islands, where it gained at the rate of $13''$, 5 a-day on mean time.

In consequence of the going of this watch, the House of Commons were pleased, in 1774, to order the other moiety of the reward offered by the act of the 12th of Queen Anne, to be given to Mr Harrison: and to enact, that any other person who, by means of a time-keeper, the principles of which had not then been made public, should enable a ship to keep her longitude during a voyage of six months, within 60 geographical miles, or a degree of a great circle, should be entitled to a reward of 5000l.; that in case he could enable her to keep her longitude for the same time within 40 geographical miles, or two-thirds of a degree of a great circle, he should be entitled to a reward of 7500l.; or to a reward of 10,000l. if he enabled her to keep it for that time, within 30 geographical miles, or half a degree of a great circle. This determination, however, ought clearly to have been in minutes of the equator; as it now is, it may be subject to numberless disputes.

Time.

This reward was in 1780 claimed by Mr Arnold, who invented a new balance spring, with a compensation for the effects of heat and cold in the balance.

It appears from this report of the going of Mr Arnold's watch, that the mean rate which it went at during the month of February 1779, was losing $0''$, 31 a-day on mean solar time: during the month of March, its mean daily loss was $1''$, 37: during the month of April, $1''$, 38; during the month of May, $1''$, 34; the month of June, $1''$, 47; July $0''$, 31; August $0''$, 55. In the month of September it gained, on mean solar time, at the rate of $0''$, 44 a-day; in October, at the rate of $0''$, 38; at the rate of $0''$, 04 in the month of November; and it lost at the rates $0''$, 50, $0''$, 68, and $0''$, 60, respectively, in the months of December 1779, January and February 1780. From hence it appears, that the parts of this machine which are to counteract the effects of heat and cold, are most exactly adjusted; and perform their office with all the regularity that can ever be expected.

It further appears, that Mr Arnold has very happily adjusted his balance, to go alike in the different positions that the watch may be put into: for we find, that when the watch was in an horizontal position, with the face upwards, it gained at the rate of $1''$, 72 a-day, on mean solar time; with the face downwards, it gained $2''$, 83: in a vertical position, with the hour XII. upwards, it gained at the rate of $0''$, 95 a-days; with the hour VI. highest, at the rate of $3''$, 85 a-days; with the hour IX. highest, at the rate of $0''$, 29 a-day; and with the hour III. highest, it lost at the rate of $0''$, 35 per day.—The greatest difference between the rates at which the watch went on any two days in these 13 months, is $6''$, 69; namely, between its rates on October 8th and December 26th. The greatest difference between its rates of going on any day, and the next to it, is $4''$, 11; namely, between the 26th and 27th of December. So that the greatest error that it would have committed in the difference of longitude on any one day, would have been very little more than one minute; which, as Mr Arnold justly observes, is determining the longitude daily, to as great precision as the latitude can in general be determined.

If we take the mean rate which it went at during the month of February 1779, as a standard rate with which we may compare its going for the following 12 months, we shall find that the greatest error which it would have committed in the longitude shown by it, would have been $2'$, $33''$, 2, or $38'$ $18''$ in longitude: and this error happened about the end of six months, or in the beginning of September; for during these six months, the watch had all along gone slower than it did in the month of February, with which rate of going it is compared; but about the beginning of September it began rather to go faster than it did in the month of February, and by that means began to lessen its total error. And it continued to do so until the latter end of November, when it began again to go slower than it had done in the month of February, and of course to increase the quantity of its total error. And this it continued to do until the latter end of February 1780, when the error appeared again to be at a maximum, and equal to $2'$ $6''$, 6 in time, or $31'$ $39''$ of longitude. After this time it rather decreased to the end of the month,

Harrison's Time-Keeper. See LONGITUDE, and the preceding article.

TIMOLEON, a celebrated Corinthian general, who restored the Syracusans to their liberty, and drove the Carthaginians out of Sicily. See SYRACUSE, n° 50—54.

TIMON, surnamed *Misanthropos*, or the *Misanth*, a famous Athenian, who lived about 420 B. C. He was one day asked, why he loved the young Alcibiades while he detested all the rest of the human race? on which he replied, "It is because I foresee that he will be the ruin of the Athenians." He carefully avoided all sorts of company; yet went one day to an assembly of the people, and cried with a loud voice, "That he had a fig-tree on which several persons had hanged themselves; but as he intended to cut it down, in order to build a house on the place where it stood, he gave them notice of it, that if any of them had a mind to hang themselves, they must make haste and do it speedily." He had an epitaph engraved on his tomb, filled with imprecations against those who read it. Shakespeare has formed an excellent tragedy on his story.

TIMOR, an island of Asia, in the East-Indian sea, to the south of the Moluccas, and to the east of the island of Java, being 150 miles in length, and 37 in breadth. It abounds in sandal-wood, wax, and honey; and the Dutch have a fort here. The inhabitants are Pagans, and are little better than savages; and some pretend they had not the use of fire many years ago.

TIMOTHEUS, one of the most celebrated poet-musicians of antiquity, was born at Miletus, an Ionian city of Caria, 446 years B. C. He was contemporary with Philip of Macedon and Euripides; and not only excelled in lyric and dithyrambic poetry, but in his performance upon the cithara. According to Pausanias, he perfected that instrument, by the addition of four new strings to the seven which it had before; though Suidas says it had nine before, and that Timotheus only added two, the tenth and eleventh, to that number. See LYRE.

With respect to the number of strings upon the lyre of Timotheus: The account of Pausanias and Suidas is confirmed in the famous *senatus-consultum* against him, still extant, preserved at full length in Boethius. Mr Stillingfleet has lately given an extract from it, in proof of the simplicity of the ancient Spartan music. The fact is mentioned in Athenæus; and Casaubon, in his notes upon that author, has inserted the whole original text from Boethius, with corrections. The following is a faithful translation of this extraordinary Spartan act of parliament. "Whereas Timotheus the Milesian, coming to our city, has dishonoured our ancient music, and despoiling the lyre of seven strings, has, by the introduction of a greater variety of notes, corrupted the ears of our youth; and by the number of his strings, and the novelty of his melody, has given to our music an effeminate and artificial dress, instead of the plain and orderly one in which it has hitherto appeared; rendering melody infamous, by composing in the chromatic instead of the enharmonic:

—The kings and the ephori have therefore resolved to pass censure upon Timotheus for these things: and, farther, to oblige him to cut all the superfluous strings of his eleven, leaving only

Timothy,
Tin.

Tindal
Tintoretto.

only the seven tones; and to banish him from our city; that men may be warned for the future not to introduce into Sparta any unbecoming custom."]

The same story, as related in Athenæus, has this additional circumstance, That when the public executioner was on the point of fulfilling the sentence, by cutting off the new strings, Timotheus, perceiving a little statue in the same place, with a lyre in his hand of as many strings as that which had given the offence, and showing it to the judges, was acquitted.

It appears from Suidas, that the poetical and musical compositions of Timotheus were very numerous, and of various kinds. He attributes to him nineteen nomes, or canticles, in hexameters; thirty-six proems, or preludes; eighteen dithyrambics; twenty-one hymns; the poem in praise of Diana; one panegyric; three tragedies, the Persians, Phinidas, and Laertes; to which must be added a fourth, mentioned by several ancient authors, called *niohe*, without forgetting the poem on the birth of Bacchus. Stephen of Byzantium makes him author of eighteen books of nomes, or airs, for the cithara, to eight thousand verses; and of a thousand *epithymia*, or preludes, for the nomes of the flutes.

Timotheus died in Macedonia, according to Suidas, at the age of ninety-seven; though the Marbles, much better authority, say at ninety; and Stephen of Byzantium fixes his death in the fourth year of the tenth Olympiad, two years before the birth of Alexander the Great; whence it appears, that this Timotheus was not the famous player on the flute so much esteemed by that prince, who was animated to such a degree by his performance, as to seize his arms; and who employed him, as Athenæus informs us, together with the other great musicians of his time, at his nuptials. However, by an inattention to dates, and by forgetting that of these two musicians of the same name the one was a Milesian and the other a Theban; they have been hitherto almost confounded.

TIMOTHY (St), the disciple of St Paul, was the son of a Gentile: but his mother was a Jewish convert. St Paul wrote two epistles to him, which are acknowledged to be canonical. St Timothy was stoned at Ephesus for opposing the worship of Diana and the superstition of the Gentiles, at one of that goddess's festivals, about the year 109.

TIN, one of the seven perfect metals. See CHEMISTRY, n° 150, 203, 246, 285, 406. See also METALLURGY.

This metal is found very plentifully in the southern parts of Britain, particularly Cornwall, to which and Devonshire the mines are now principally confined. Though in itself the lightest, it is in its ore the heaviest of all the metals. It is very seldom, if ever, found pure, and the appearances of its ore are very different. The finest and richest are styled *tin grains*, or *corns of tin*, being crystals of a black colour of different sizes. It is also found in a heavy black stone, sometimes in a more porous yellow-coloured one, and is commonly intermixed with spar, arsenic, &c. Tin-mines are generally found on the sides of the hills, though veins sometimes pass through valleys or brooks between two hills, and may be traced to the opposite hill. The miners work with the utmost difficulty through hard rocks from three to 70 fathoms depth;

VOL. X.

and it is no less troublesome, as well as dangerous, where the earth is loose and apt to crumble. The veins are of an uncertain thickness; from three inches to three feet. Tin grains or corns of tin yield five parts in eight of metal; whereas tin stones yield only from one in 30 to one in 60, and to one in 120; for these last are also wrought with some small profit.

After melting it is called *black tin*; but before it can be exposed to sale it is carried to one of the five coinage-towns, where, after examination of a piece that is broke from the corner of a block, the arms of the duchy of Cornwall are impressed with an hammer, and then it is called *white tin*. The duty on coinage, which is four shillings on the hundred-weight, belongs to the prince of Wales as duke of Cornwall, and produces a revenue of upwards of 10,000*l.* per annum.

TINDAL (Dr Matthew), a famous English writer, was the son of the reverend Mr John Tindal of Beer-Ferres in Devonshire, and was born about the year 1657. He studied at Lincoln college in Oxford, whence he removed to Exeter, and was afterwards elected fellow of All Souls. In 1683; he took the degree of doctor of law, and in the reign of James II. declared himself a Roman Catholic; but soon renounced that religion. After the Revolution he published several pamphlets in favour of government, the liberty of the press, &c. His "Rights of the Christian Church asserted," occasioned his having a violent contest with the high-church clergy, and his treatise "Christianity as old as the Creation," published in 1730, made much noise, and was answered by several writers, particularly by Dr Conybeare, Mr Forster, and Mr Leland. Dr Tindal died at London in August 1733. He left in manuscript a second volume of his "Christianity as old as the Creation;" the preface to which has been published. Mr Pope has satyrized Dr Tindal in his *Dunciad*.

TINDALE, or TYNDALE. See TYNDALE.

TINE. There are two rivers of this name; the one called *North Tine*, which rises on the borders of Scotland; and the other called *South Tine*, which rises on the confines of Cumberland; the one running south-east, and the other north-east. They unite their waters at Hexham; and continuing to run east, divide the counties of Durham and Northumberland, passing by Newcastle, and falling into the German sea at Timouth.

TINNING, the covering or lining any thing with melted tin, or tin reduced to a very fine leaf. Looking-glasses are foliated or tinned with thin plates of beaten tin, the whole bigness of the glass, applied or fastened thereto by means of quicksilver. See FOLIATING.

TINNITUS AURIUM, a noise in the ears like the continued sound of bells, very common in many disorders, particularly in nervous fevers.

TINTORETTO, so called from being the son of a dyer, but whose proper name was *Giacomo Robusti*; was an excellent painter, born at Venice in 1512. He was a disciple of Titian; who having observed something extraordinary in his genius, dismissed him from his family, for fear he should become his rival: yet he adhered to Titian's manner of colouring as the most natural, while he studied Michael Angelo's gusto

43 G of

Tipperary of designing as the most correct. He was called the *Furious Tintoret*, from his bold manner of painting, with strong lights and deep shadows; from the rapidity of his genius; and from his grand vivacity of spirit, so much admired by Paul Veronese. Venice was the place of his constant abode, where he was made a citizen, and was wonderfully beloved: he died in 1594. Tintoret had a son and a daughter, both of whom excelled in the art of painting; his daughter Maria especially, who was eminent for an admirable style in portraits, and for her musical talents. She married a German, and died in 1530. Dominico his son gave great hopes in his youth of being a considerable portrait-painter; but fell short by neglecting his talents: he died in 1637.

TIPPERARY, a county of the province of Munster in Ireland, bounded on the west by that of Limerick and the river Shannon, on the east by the county of Kilkenny, on the south by the counties of Cork and Waterford, and on the north and north-east by King's-county and the territory of the ancient O'Carols. It extends about 60 miles in length, 36 in breadth, containing 599,600 acres, divided into 14 baronies, in which are several market-towns and boroughs. It sends eight members to parliament, viz. two for the county, two for the city of Cashel, and two for each of the boroughs of Clonmell, Fethard, and Thurles. The north part of it is mountainous and cold; but in the south the air is milder, and the soil much more fertile, producing plenty of corn, and good pasture for the numerous herds of cattle and flocks of sheep with which it abounds. The north part is called *Ormond*, and for a long time gave the title of *earl*, and afterwards of *marquis and duke*, to the noble family of Butler, descended from a sister of Thomas a Becket archbishop of Canterbury, till, at the accession of George I. the last duke was attainted of high-treason, and died abroad. In that part of the county, the family had great prerogatives and privileges granted them by Edward III. Another district in this county was anciently called the *county of the Holy Cross of Tipperary*, from a famous abbey in it styled *Holy Cross*, on account of a piece of Christ's cross that was said to be preserved there. This abbey and district enjoyed also special privileges in former times. The remains of the abbey, or rather the spot where it stood, are still held in great veneration, and much resorted to by the Roman Catholics.

TIPSTAFF, an officer who attends the judges with a kind of staff tipped with silver, and takes into his charge all prisoners who are committed or turned over at a judge's chambers.

TIPULA, the CRANE-FLY; a genus of insects belonging to the order of diptera. The mouth is a prolongation of the head; the upper-jaw is arched. They have two palpi, which are curved, and longer than the head. The proboscis is short, and bends inwards. They are divided into two families. 1. Those with wings displayed. 2. Those with wings incumbent, and which in form resemble a gnat.

This two-winged insect is often taken for the gnat, which it resembles, but has not its mischievous instinct, nor its murderous proboscis. The larger tipulæ go by the name of *sensitiffes*, the small ones by that of *caliciform*; which latter, in fine summer-evenings, flutter

about the water-side in legions, through which a person may pass on his way unhurt. The shrill noise they make with their wings is not very discernible. Tipulæ, before they become inhabitants of the air, creep under the form of grubs. Those which turn to larger tipulæ dwell in holes of decayed willows, in the dampest places, where they change into chrysalids, and in that state have the faculty of breathing through two small curve horns; besides which they are endowed with progressive motion, but not retrogressive, being impeded by little spines placed on every ring of the abdomen. When the shroud is torn, the insect, prettily apparelled, escapes from his gloomy habitation by means of his wings, which often are variegated, and takes his pasture in the fields. Its long legs, and its wings, mutually assist each other when it either walks or flies. The larvæ and chrysalids of the little tipulæ are found in water. They are various in colour, form, and carriage; some being grey, others brown, and others red; some, like the polypus, furnished with a pair of arms; several with cylindrical tubes that perform the office of vent-holes. These swim with nimbleness; those never leave the holes they have dug themselves in the banks of rivulets. Lastly, others make a silken cocoon that receives part of their body; but all of them, after a period, renounce their reptile and aquatic life, and receive wings from the hands of nature. Their frame is then so weak, that a touch is enough to crush them. They are sometimes of a beautiful green, sometimes coal-black; and the most remarkable are those whose fore-legs, extraordinarily long, do not touch the ground, and are moveable like antennæ. In this state of perfection, the tipulæ being provided with proper organs, apply themselves to the propagation of the species. Those same poor insects, who in the state of larvæ have escaped the voraciousness of fishes, often become, in their progress through the air, a prey to equally merciless birds.

TIRE, in the sea-language, is a row of cannon placed along a ship's side, either above upon deck, or below, distinguished by the epithets of *upper and lower tires*.

TIRESIAS, a famous soothsayer of antiquity, was the son of Evros and the nymph Chariclo. Phercydes says, that Minerva being accidentally seen by Tiresias, as she was bathing with Chariclo in the fountain of Hippocrene, the goddess was enraged, and declared that he should see nothing more, on which he instantly lost his sight: but afterwards received from the goddesses superior endowments. Others say, that Juno struck him stone-blind for deciding a case between Jupiter and her, to her dissatisfaction; for which Jupiter gave him the faculty of divination: He was the most celebrated prophet in the Grecian annals. Ulysses is ordered by Circe to consult him in the shades.

There seek the Theban bard depriv'd of sight,
Within irradiate with prophetic light.

But, besides the honour done to him by Homer, Sophocles makes him act a venerable and capital part in his tragedy of Oedipus. Callimachus ascribes to Minerva the gift of his superior endowments; the pre-eminence of his knowledge is likewise mentioned by Tully in his first book of Divination. And not only Tiresias is celebrated by Diodorus Siculus, but his daughter Daphne, who, like her father, was gifted with

a prophetic spirit, and was appointed priestess at Delphos. She wrote many oracles in verse, from whence Homer was reported to have taken several lines, which he interwove in his poems. As she was often seized with a divine fury, she acquired the title of *sybil*, which signifies "enthusiast." She is the first on whom it was bestowed: in after-times this denomination was given to several other females that were supposed to be inspired, and who uttered and wrote their predictions in verse; which verse being sung, their function may be justly said to unite the priesthood with prophecy, poetry, and music.

TIROL, or TYROL, a county of Austria, under which may be included the territories belonging to the bishops of Brixen, Trent, and Chur, Teutonic Order, and the prince of Deitrichstein, the Austrian feignories before the Arlberg, and the Austrian districts in Swabia.

This county, with regard to the face of it, is very mountainous. Of these mountains, some have their tops always buried in snow; others are covered with woods, abounding with a variety of game; and others are rich in metals, and marble of all colours. Of the lower, some yield plenty of corn, others wine, and woods of chestnut trees. The valleys are exceeding fertile also, and pleasant. In some places considerable quantities of flax are raised, in others there is a good breed of horses and horned cattle; and, among the mountains, abundance of chamois and wild goats. In this country are also found precious stones of several sorts, as granates, rubies, amethysts, emeralds, and a species of diamonds, agates, cornelians, chalcedonies, malachites, &c. nor is it without hot-baths, acid waters, salt-pits, mines of silver, copper, and lead, mineral colours, alum, and vitriol. The principal river of Tyrol is the Inn, which after traversing the country, and receiving a number of lesser streams into it, enters Bavaria, in which, at Passau, it falls into the Danube. The men here are very tall, robust, and vigorous; the women also are stout, and generally fair: and both sexes have a mixture of the Italian and German in their tempers and characters. As there is little trade or manufacture in the country, except what is occasioned by the mines and salt-works, many of the common people are obliged to seek a subsistence elsewhere. A particular kind of salutation is used all over Tyrol. When a person comes into a house, he says, "Hail! Jesus Christ!" the answer is, "May Christ be praised, and the Holy Virgin his mother." Then the master of the house takes the visitor by the hand. This salutation is fixed up in print at all the doors, with an advertisement tacked to it, importing, that pope Clement XI. granted an hundred days indulgence, and a plenary absolution, to those who should pronounce the salutation and answer, as often as they did it. The emperor has forts and citadels so advantageously situated on rocks and mountains all over the country, that they command all the valleys, avenues, and passes that lead into it. The inhabitants, however, to keep them in good humour, are more gently treated, and not so highly taxed as those of the other hereditary countries. As to the states they are much the same in this country as in the other Austrian territories, except that the peasants here send deputies to the diets. Tyrol came to the house of Austria in the year 1363, when

Margaret, countess thereof, bequeathed it to her uncles the dukes of Austria. The arms of Tyrol are an eagle gules, in a field argent. The counts of Trap are hereditary stewards; the lords of Gloetz, chamberlains; the princes of Trautson, marshals; the counts of Wolkenstein, masters of the horse and carvers; the house of Spaur, cup-bearers; the counts of Kunigl, stewards and rangers; the counts of Brandis, keepers of the jewels; the house of Welfperg, purveyors and staff-bearers; and the counts of Coalto, falconers. Besides the governor, here are three sovereign colleges, subordinate to the court at Vienna, which sit at Inspruck, and have their different departments. Towards the expences of the military establishment of this county, the proportion is 100,000 florins yearly; but no more than one regiment of foot is generally quartered in it.

Tyrol is divided into six quarters, as they are called, namely, those of the Lower and Upper Inthal, Vintigow, Etch, Eisack, and Pustertthal.

TITAN, in fabulous history, the son of Cælus and Terra, and the eldest brother of Saturn, suffered the latter to enjoy the crown, on condition that he should bring up none of his male issue, by which means the crown would at length revert to him; but Jupiter being spared by the address of Rhea, Saturn's wife, Titan and his children were so enraged at seeing their hopes frustrated, that they took up arms to revenge the injury; and not only defeated Saturn, but kept him and his wife prisoners, till he was delivered by Jupiter, who defeated the Titans; when from the blood of these Titans slain in the battle, proceeded serpents, scorpions, and all venomous reptiles. See SATURN.

TITHES, in ecclesiastical law, are defined to be the tenth-part of the increase, yearly arising and renewing from the profits of lands, the stock upon lands, and the personal industry of the inhabitants: the first species being usually called *predial*, as of corn, grass, hops, and wood; the second *mixed*, as of wool, milk, pigs, &c. consisting of natural products, but nurtured and preserved in part by the care of man; and of these the tenth must be paid in gross: the third *personal*, as of manual occupations, trades, silviculture, and the like; and of these only the tenth part of the clear gains and profits is due.

We shall, in this article, consider, 1. The original of the right of tithes. 2. In whom that right at present subsists. 3. Who may be discharged, either totally or in part, from paying them.

1. As to their original, we will not put the title of the clergy to tithes upon any divine right; though such a right certainly commenced, and we believe as certainly ceased, with the Jewish theocracy. Yet an honourable and competent maintenance for the ministers of the gospel, is undoubtedly *jure divino*, whatever the particular mode of that maintenance may be. For, besides the positive precepts of the New Testament, natural reason will tell us, that an order of men who are separated from the world, and excluded from other lucrative professions for the sake of the rest of mankind, have a right to be furnished with the necessaries, conveniences, and moderate enjoyments of life, at their expence; for whose benefit they forego the usual means of providing them. Accordingly all municipal laws have provided a liberal and decent maintenance for their national priests or clergy: ours, in parti-

Tithes.

particular, have established this of tithes, probably in imitation of the Jewish law : and perhaps, considering the degenerate state of the world in general, it may be more beneficial to the English clergy to found their title on the law of the land, than upon any divine right whatsoever, unacknowledged and unsupported by temporal sanctions.

We cannot precisely ascertain the time when tithes were first introduced into this country. Possibly they were cotemporary with the planting of Christianity among the Saxons by Augustin the monk, about the end of the sixth century. But the first mention of them which we have met with in any written English law, is a constitutional decree, made in a synod held A. D. 786, wherein the payment of tithes in general is strongly enjoined. This canon or decree, which at first bound not the laity, was effectually confirmed by two kingdoms of the heptarchy, in their parliamentary conventions of estates, respectively consisting of the kings of Mercia and Northumberland, the bishops, dukes, senators, and people. Which was a few years later than the time that Charlemagne established the payment of them in France, and made that famous division of them into four parts ; one to maintain the edifice of the church, the second to support the poor, the third the bishop, and the fourth the parochial clergy.

The next authentic mention of them is in the *sedes Edwardi et Guthruni* ; or the laws agreed upon between king Guthrun the Dane, and Alfred and his son Edward the Elder, successive kings of England, about the year 900. This was a kind of treaty between those monarchs, which may be found at large in the Anglo-Saxon laws : wherein it was necessary, as Guthrun was a Pagan, to provide for the subsistence of the Christian clergy under his dominion ; and accordingly, we find the payment of tithes not only enjoined, but a penalty added upon non-observance : which law is seconded by the laws of Athelstan, about the year 930. And this is as much as can certainly be traced out with regard to their legal original.

2. Upon the first introduction, though every man was obliged to pay tithes in general, yet he might give them to what priests he pleased ; which were called *arbitrary consecrations of tithes* ; or he might pay them into the hands of the bishop, who distributed among his diocesan clergy the revenues of the church, which were then in common. But when dioceses were divided into parishes, the tithes of each parish were allotted to its own particular minister ; first by common consent or the appointments of lords of manors, and afterwards by the written law of the land.

However, arbitrary consecrations of tithes took place again afterwards, and became in general use till the time of king John. Which was probably owing to the intrigues of the regular clergy, or monks of the Benedictine and other rules, under archbishop Dunstan and his successors ; who endeavoured to wean the people from paying their dues to the secular or parochial clergy, (a much more valuable set of men than themselves), and were then in hopes to have drawn, by sanctimonious pretences to extraordinary purity of life, all ecclesiastical profits to the coffers of their own societies. And this will naturally enough account for the number and riches of the monasteries and religious

houses which were founded in those days, and which were frequently endowed with tithes. For a layman, who was obliged to pay his tithes somewhere, might think it good policy to erect an abbey, and there pay them to his own monks, or grant them to some abbey already erected : since for this donation, which really cost the patron little or nothing, he might, according to the superstition of the times, have masses for ever sung for his soul. But in process of years, the income of the poor laborious parish-priests being scandalously reduced by these arbitrary consecrations of tithes, it was remedied by pope Innocent III. about the year 1200, in a decretal epistle sent to the archbishop of Canterbury, and dated from the palace of Lateran : which has occasioned Sir Henry Hobart and others to mistake it for a decree of the council of Lateran, held A. D. 1179, which only prohibited what was called the *infodation of tithes*, or their being granted to mere laymen ; whereas this letter of pope Innocent to the archbishop enjoined the payment of tithes to the parsons of the respective parishes where every man inhabited, agreeable to what was afterwards directed by the same pope in other countries. This epistle, says Sir Edward Coke, bound not the lay subjects of this realm ; but being reasonable and just, it was allowed of, and so became *lex terræ*. This put an effectual stop to all the arbitrary consecrations of tithes ; except some footsteps which still continue in those portions of tithes which the parson of one parish hath, though rarely, a right to claim in another : for it is now universally held, that tithes are due, of common right, to the parson of the parish, unless there be a special exemption. This parson of the parish may be either the actual incumbent, or else the appropriator of the benefice : appropriations being a method of endowing monasteries, which seems to have been devised by the regular clergy, by way of substitution to arbitrary consecrations of tithes.

Lands and their occupiers may be exempted or discharged from the payment of tithes, either in part or totally, first, by a real composition ; or, secondly, by custom or prescription.

First, a real composition is when an agreement is made between the owner of the lands and the parson or vicar, with the consent of the ordinary and the patron, that such lands shall for the future be discharged from payment of tithes, by reason of some land or other real recompense given to the parson in lieu and satisfaction thereof. This was permitted by law, because it was supposed that the clergy would be no losers by such composition ; since the consent of the ordinary, whose duty it is to take care of the church in general, and of the patron, whose interest it is to protect that particular church, were both made necessary to render the composition effectual : and hence have arisen all such compositions as exist at this day by force of the common law. But experience showing that even this caution was ineffectual, and the possessions of the church being by this and other means every day diminished, the disabling statute 13 Eliz. c. 10. was made ; which prevents, among other spiritual persons, all parsons and vicars from making any conveyances of the estates of their churches, other than for three lives or 21 years. So that now, by virtue of this statute, no real composition made since the 13 Eliz. is good for any longer

Tithes.

Tithes.

term than three lives or 21 years, though made by consent of the patron and ordinary: which has indeed effectually demolished this kind of traffic; such compositions being now rarely heard of, unless by authority of parliament.

Secondly, a discharge by custom or prescription, is where time out of mind such persons or such lands have been, either partially or totally, discharged from the payment of tithes. And this immemorial usage is binding upon all parties; as it is in its nature an evidence of universal consent and acquiescence, and with reason supposes a real composition to have been formerly made. This custom or prescription is either *de modo decimandi*, or *de non decimando*.

A *modus decimandi*, commonly called by the simple name of a *modus* only, is where there is by custom a particular manner of tithing allowed, different from the general law of taking tithes in kind, which are the actual tenth-part of the annual increase. This is sometimes a pecuniary compensation, as twopence an acre for the tithe of land: sometimes it is a compensation in work and labour, as that the parson shall have only the twelfth cock of hay, and not the tenth, in consideration of the owner's making it for him: sometimes, in lieu of a large quantity of crude or imperfect tithe, the parson shall have a less quantity when arrived to greater maturity, as a couple of fowls in lieu of tithe-eggs, and the like. Any means, in short, whereby the general law of tithing is altered, and a new method of taking them is introduced, is called a *modus decimandi*, or special manner of tithing.

A prescription *de non decimando* is a claim to be entirely discharged of tithes, and to pay no compensation in lieu of them. Thus the king by his prerogative is discharged from all tithes. So a vicar shall pay no tithes to the rector, nor the rector to the vicar, for *ecclesia decimas non solvit ecclesie*. But these personal privileges (not arising from or being annexed to the land) are personally confined to both the king and the clergy; for their tenant or lessee shall pay tithes, tho' in their own occupation their lands are not generally tithable. And, generally speaking, it is an established rule, that in lay hands, *modus de non decimando non valet*. But spiritual persons or corporations, as monasteries, abbots, bishops, and the like, were always capable of having their lands totally discharged of tithes by various ways: as, 1. By real composition. 2. By the pope's bull of exemption. 3. By unity of possession; as when the rectory of a parish, and lands in the same parish, both belonged to a religious house, those lands were discharged of tithes by this unity of possession. 4. By prescription; having never been liable to tithes, by being always in spiritual hands. 5. By virtue of their order; as the Knights Templars, Cistercians, and others, whose lands were privileged by the pope with a discharge of tithes. Though, upon the dissolution of abbeyes by Henry VIII. most of these exemptions from tithes would have fallen with them, and the lands become tithable again, had they not been supported and upheld by the statute 31 Henry VIII. c. 13. which enacts, that all persons who should come to the possession of the lands of any abbey then dissolved, should hold them free and discharged of tithes, in as large and ample a manner as the abbeyes themselves formerly held them. And from this original have

sprung all the lands which, being in lay hands, do at present claim to be tithe-free: for if a man can show his lands to have been such abbey-lands, and also immemorially discharged of tithes by any of the means before-mentioned, this is now a good prescription *de non decimando*. But he must show both these requisites: for abbey-lands, without a special ground of discharge, are not discharged of course; neither will any prescription *de non decimando* avail in total discharge of tithes, unless it relates to such abbey-lands.

TITHING, (*Tithinga*, from the Sax. *Theothunga*, i. e. *Decuriam*), is in its first appointment the number or company of ten men with their families, held together in a society, all being bound for the praeable behaviour of each other; and of these companies there was one chief person, who was called *teothung-man*, at this day *tithing-man*: but the old discipline of tithings is long since left off. In the Saxon times, for the better conservation of the peace, and more easy administration of justice, every hundred was divided into ten districts or tithings; and within every tithing, the tithing-men were to examine and determine all lesser causes between villages and neighbours; but to refer greater matters to the then superior courts, which had a jurisdiction over the whole hundred.

TITHING-MEN, are now a kind of petty constables, elected by parishes, and sworn in their offices in the court-leet, and sometimes by justices of the peace, &c. There is frequently a tithing-man in the same town with a constable, who is as it were a deputy to execute the office in the constable's absence; but there are some things which a constable has power to do, that tithing-men and head-boroughs cannot intermeddle with. When there is no constable of a parish, the office and authority of a tithing-man seems to be all one under another name.

TITHONUS, in fabulous history, the son of Laomedon king of Troy, and the brother of Priamus; was beloved by Aurora, who carried him to Delos, thence to Ethiopia, and at last to heaven, where she prevailed on the Destinies to bestow upon him the gift of immortality; but forgot to add that of youth, which could only render the present valuable. At length Tithonus grew so old that he was obliged to be rocked to sleep like an infant, when Aurora, not being able to put an end to his misery by death, transformed him into a grasshopper; which renews its youth by casting his skin, and in his chirping retains the loquacity of old age.

TITIANO, or TITIAN, the most universal genius for painting of all the Lombard school, the best colourist of all the moderns, and the most eminent for histories, portraits, and landscapes, was born at Cadore, in the province of Friuli, in the state of Venice, in 1477. His parents sent him at ten years of age to one of his uncles at Venice, who finding that he had an inclination to painting, put him to the school of Giovanni Bellini, where he greatly improved himself, by his endeavouring to excel Giorgione his fellow disciple, and became the greatest colourist ever known. He designed with much greater ease than Giorgione. Some of his women and children, says du Fresnoy, are admirable both for the design and colouring; they are in a delicate and noble gusto, with a certain pleasing negligence of the head-dresses, draperies, and ornaments

Tithing
||
Titiano.

Titiano,
Title.

of the habits peculiar to him. However, the figures of his men are designed but moderately well, and some of their draperies are mean. His painting is wonderfully glowing, sweet, and delicate. He made portraits that were extremely noble; the attitudes being very graceful, grave, and adorned after a becoming manner. Nobody ever painted landscapes with so great a manner, so good a colouring, and with such a resemblance of nature. For eight or ten years he took the pains to copy with great exactness whatever he performed, in order to obtain an easy method, and to establish some general maxims for his future conduct. Besides his excellent gusto in colours, in which he excelled all mankind, he perfectly understood how to give every thing the touches most proper and suitable to it, such as distinguish them from each other, and which give the greatest spirit and the most of truth. He was, however, censured by Michael Angelo Buonarroti for want of correctness in design, a fault common to all the Lombard painters who had not been acquainted with the antiques, yet that defect was abundantly supplied by his being master of all the other parts of an accomplished artist.

Titian made three portraits of the emperor Char. V. who honoured him with knighthood, created him count palatine, made all his descendants gentlemen, and assigned him a considerable pension out of the chamber of Naples. It is said this emperor one day took up a pencil that Titian dropped when drawing his picture; and that upon the compliment made him by the artist on this occasion, he replied, "Titian deserves to be served by Cæsar." In short, some of that emperor's courtiers being unable to conceal their jealousy on the visible preference he showed to Titian's person and conversation, the emperor told them, that he could never want courtiers, though he might a Titian. He accordingly loaded him with wealth; and whenever he sent him money, he did it with this obliging observation, That it was not to pay him the value of his pictures, because that was above all price. Titian also painted that emperor's son Philip II. Solymann emperor of the Turks, three kings, two empresses, several queens, two popes, and almost all the princes of Italy; and so great was his reputation, that there was hardly a person of any eminence in Europe from whom he did not receive some marks of esteem; for being of an obliging and generous temper, his house at Venice was the constant rendezvous of all the virtuosi and people of quality. He was of so happy a constitution, that he was never ill till the year 1576, when he died of the plague, at 99 years of age. His disciples were Paolo Veronese, Giacomo Tintoret, Giacomo de Ponte Baffano, and his sons.

Horatio, Titian's youngest son, painted several portraits that might stand in competition with those of his father. He was also famous for many history-pieces, which he executed at Venice in concurrence with Paul Veronese and Tintoret: but, bewitched at last with alchemy, he laid aside his pencil, and, in search of the philosophers' stone, converted all his paternal inheritance into smoke.

TITLE, an appellation of dignity or quality, given to princes and other persons of distinction. Thus the title of his Britannic majesty is, *King of Great Britain, France, and Ireland*; that of the French king is,

King of France and Navarre: and so of others. The pope assumes the title of *Holiness*, and the cardinals that of *Eminence*, &c.

TITLE, in law, denotes any right which a person has to the possession of a thing, or an authentic instrument whereby he can prove his right. See the articles, RIGHT, PROPERTY, &c.

TITLE to the Crown in the British Constitution. See SUCCESSION.

TITMOUSE, in ornithology. See PARUS.

TITULAR, denotes a person invested with a title, in virtue of which he holds an office or benefice, whether he perform the functions thereof or not.

TITUS VESPASIANUS, the Roman emperor, the son of Vespasian; of whom it is related, that not being able to recollect any remarkable good action he had done on a certain day, he exclaimed, "I have lost a day!" He might truly be called the *father of his people*; and though Rome laboured under various public calamities during his reign, such was his equitable and mild administration, that he constantly preserved his popularity. He was a great lover of learning, and composed several poems. He reigned but two years; and it is thought Domitian his brother poisoned him, A. D. 81, aged 41. See (*History of*) ROME.

TIVIOT, or CHEVIOT, HILLS, are high hills in the county of Northumberland in England.

TOAD, in zoology. See RANA.

TOAD-Fish. See LOPHIUS.

TOAD-Flax, in botany. See ANTIRRHINUM.

TOBACCO, in botany. See NICOTIANA.

TOBACCO-Pipe-Fish. See FISTULARIA.

TOBAGO, one of the Caribbee islands, ceded to Great Britain by the treaty of Paris in 1763, but taken by the French in the course of last war. It lies in the latitude of 11 degrees 10 minutes north, and 59 degrees 40 minutes longitude west from London, about 40 leagues south-by-west from Barbadoes, 35 south-east from St Vincents, 20 south-east from Grenada, 12 north-east from the Spanish island of Trinidad, and between 30 and 40 north-east from the Spanish main. According to the latest accounts, it is somewhat more than 30 miles in length from north-east to south-west, between 8 and 9 in breadth, and from 23 to 25 leagues in circumference. The English visited this island very early, Sir Robert Dudley being there in the reign of queen Elizabeth. In that of Charles I. William Earl of Pembroke procured a grant of this, with two other small islands; but died before he was able to carry into execution his design of settling them. In A. D. 1632 some merchants of Zealand sent over a small colony thither, and gave it the name of *New Walcheren*; but before they were able thoroughly to establish themselves, they were destroyed by the Indians assisted by the Spaniards. Ten years after, James Duke of Courland sent a colony thither, who settled themselves upon Great Courland bay, and made a considerable progress in planting. A. D. 1654, Messieurs Adrian and Cornelius Lampins, two opulent merchants of Flushing, sent a considerable number of people thither, who settled on the other side of the island, and lived in amity with the Courlanders until they learned that the king of Sweden had seized the person of their duke and dispossessed him of his dominions, when they attacked and forced his subjects to submit.

Tobolski.

submit. The duke being afterwards restored, he obtained from Charles II. a grant, dated the 17th of November 1664, of this island. In the second Dutch war the count d'Estrees, by order of his master, totally ruined it at the close of the year 1677, and from that time it continued waste till we took possession of it after the treaty of Paris. The climate, notwithstanding its vicinity to the line, is so tempered by the breezes from the sea, as to be very supportable even to Europeans; and hath the same advantages with that of Grenada, in having regular seasons, and also in being exempt from the hurricanes. There are throughout the island many rising grounds, though, except at the north-east extremity, there is no part of it that can be styled mountainous, and even there the country is far from being rugged or impassable. The soil, if we may credit either Dutch or French writers, is as fertile and luxuriant as any of the islands, and very finely diversified. Ground provisions of all sorts have been raised in great plenty, a vast variety of vegetables, excellent in their kind, some for food, some for physic. Almost every species of useful timber is to be found here, and some of an enormous size; amongst others, the true cinnamon and nut-meg tree, as the Dutch confess, and of which none could be better judges; whole groves of salafra, and of trees that bear the true gum copal, with other odoriferous plants that render the air wholesome and pleasant. It is as well watered as can be wished, with rivers that fall into the sea on both sides, many smaller streams, and fine fresh springs in almost every part of the island. The sea-coast is indented by 10 or 12 fair and spacious bays, and there are amongst these one or two ports capable of receiving as large ships as ever visited those seas. There are wild hogs in great plenty, abundance of fowls of different kinds, and a vast variety of sea and river fish. At the north-east extremity lies Little Tobago, which is two miles long, and about half a mile broad, very capable of improvement.

TOBOLSKI, the capital of Siberia, is situated at the confluence of the rivers Tobol and Irtysh, in N. Lat. 58. E. Long. 63. The city stands upon the ascent of a high hill, the lower part of which is inhabited by Mahometan Tartars, who carry on a considerable traffic upon the river Irtysh, and convey their merchandise quite across Great Tartary, as far as China. The river Irtysh is reckoned as rapid as the Danube; runs from the south, and empties itself into the Ob; the Tobol washes the other side of the town, and a little below it falls into the Irtysh. By means of these two rivers, there is a constant flow of merchandise into the city during the summer-season. Tobolski is therefore a great mart for the commodities of Muscovy, Tartary, and other countries; and here is a great concourse of merchants. All sorts of provisions are plentiful and cheap. An hundred weight of rice is sold for sixteen copeks, equal to about eightpence sterling; a sturgeon, weighing forty pounds, for half that money; an ox for two rix-dollars, and every other article in proportion: the adjacent country abounds with game in great variety. The supreme court of judicature for all Siberia is held in this city, which is also the seat of a metropolitan, sent hither from Moscow to exercise spiritual jurisdiction over the whole kingdom. Tobolski is well fortified,

and defended by a strong garrison, under the command of the waiwode, who resides in the place, and takes charge of the fur tribute, which is here deposited in proper magazines. This governor enjoys a very extensive command, and can occasionally bring into the field nine thousand men, besides a strong body of Tartars on horseback, to make head against the Khalmucks and Cossacks, in their repeated incursions. A sufficient number of Russians, called *Jermkoiks*, are kept in continual pay by the government, on the banks of the Irtysh, to supply travellers on the czar's account with men, boats, or carriages, to convey them as far as Surgut on the Ob, a voyage of two hundred leagues by water. This is the common method of travelling in the summer; but in winter the journey by land is not half so long, being performed in sleds over the ice and snow, with which the country is covered. These sleds are moved by a pair of dogs, which will draw a load of three hundred pounds with surprising expedition. They are hired at easy rates, and during one half of the year may be seen flying over the snow in great numbers.

TOCKAY, a very strong town of Upper Hungary, in the county of Zimplin, with a castle. It is noted for its excellent wine, which is produced but in one vineyard, inasmuch that it is scarce at Vienna itself; so that it is no wonder to find other wines often sold for it. Some distance from the town are large salt-works. It is seated at the confluence of the rivers Bodrag and Teisse. E. Long. 21. 5. N. Lat. 48. 0.

TODDY. See ARACK.

TOGA, in Roman antiquity, a wide woollen gown or mantle; which seems to have been of a semicircular form, without sleeves; differing both in richness and largeness, according to the circumstances of the wearer, and used only upon occasion of appearing in public.

Every body knows that the toga was the distinguished mark of a Roman; hence, the *jus togæ*, or privilege of a Roman citizen; *i. e.* the right of wearing a Roman habit, and of taking, as they explain it, fire and water through the Roman empire.

TOISE, a French measure containing six of their feet, or a fathom.

TOLAND (John), a very famous writer, was born near Londonderry in Ireland, 1670, and educated in the Popish religion; but at sixteen years of age embraced the principles of the Protestants. He studied three years at the university of Glasgow; was created master of arts in the university of Edinburgh; and afterwards completed his studies at Leyden, where he resided two years. He then went to Oxford, where, having the advantage of the public library, he collected materials upon various subjects, and composed some pieces, among which was, A Dissertation to prove the received history of the tragical death of Atilius Regulus, the Roman consul, to be a fable. He began likewise a work of greater consequence, in which he undertook to show that there are no mysteries in the Christian religion. He published it in 1696 at London, under the title of *Christianity not mysterious*. This book gave great offence, and was attacked by several writers. He afterward wrote in favour of the Hanoverian succession, and many other pieces. In 1717 he went into Germany, where he vi-

Toledo,
Toleration.

sited several courts; and in 1710 he was introduced to prince Eugene, who gave him several marks of his generosity. Upon his return to England he was for some time supported by the liberality of the earl of Oxford lord-treasurer, and kept a country-house at Epfom; but soon losing his lordship's favour, he published several pamphlets against that minister's measures. In the four last years of his life he lived at Putney, but used to spend most part of the winter in London. Mr Toland died at London in 1722. He was a man of uncommon abilities, published a number of curious tracts, and was perhaps the most learned of all the infidel writers: but his private character was far from being an amiable one; for he was extremely vain, and wanted those social virtues which are the chief ornaments as well as duties of life. His posthumous works, 2 vols 8vo, were published in 1726, with an account of his life and writings, by Mr Desmaizeaux.

TOLEDO, an ancient and trading city of Spain in New Castile, of which it was formerly the capital. It is advantageously seated on the river Tajo, which surrounds it on two sides; and on the land-side it has an ancient wall built by a Gothic king, and flanked with 100 towers. It is seated on a mountain, which renders the streets uneven, and which are narrow; but the houses are fine, and there are a great number of superb structures, besides 17 public squares, where the markets are kept. The finest buildings are the royal castle and the cathedral church; which last is the richest and most considerable in Spain. It is seated in the middle of the city, joining to a handsome street, with a fine square before it. Several of the gates are very large, and of bronze. There is also a superb steeple extremely high, from whence there is a very distant prospect. The Sagrario, or principal chapel, is a real treasury, in which are 15 large cabinets let into the wall, full of prodigious quantities of gold and silver vessels, and other works. There are two mitres of silver gilt, set all over with pearls and precious stones, with three collars of massy gold, enriched in like manner. There are two bracelets and an imperial crown of the Virgin Mary, consisting of large diamonds and other jewels. The weight of the gold in the crown is 15 pounds. The vessel which contains the consecrated wafer is of silver gilt, as high as a man, and so heavy, that it requires 30 men to carry it; within it is another of pure gold enriched with jewels. Here are 38 religious houses, most of which are worthy a traveller's notice, with many other sacred buildings, a great number of churches belonging to 27 parishes, and some hospitals. Without the town are the remains of an amphitheatre, and other antiquities. It is an archbishop's see, has a famous university, and several manufactories of silk and wool. It is very pleasantly seated in E. Long. 3. 15. N. Lat. 43. 6.

TOLERATION, in matters of religion, is either civil or ecclesiastical. Civil toleration is an impunity and safety granted by the state to every sect that does not maintain doctrines inconsistent with the public peace: and ecclesiastical toleration is the allowance which the church grants to its members to differ in certain opinions, not reputed fundamentals. See NON-CONFORMISTS.

On the subject of religious toleration, we have the

following observations in Dr Robertson's history of Charles V. "Among the ancient heathens, all whose deities were local and tutelary, diversity of sentiments concerning the objects or rites of religious worship seems to have been no source of animosity; because the acknowledging veneration to be due to one God, did not imply a denial of the existence or the power of any other god; nor were the modes and rites of worship established in one country incompatible with those which other nations approved and observed. Thus the errors in their system of theology were of such a nature as to be productive of concord; and notwithstanding the amazing number of their deities, as well as the infinite variety of their ceremonies, a sociable and tolerating spirit subsisted almost universally in the Pagan world.

"But when the Christian revelation declared one Supreme Being to be the sole object of religious veneration, and prescribed the form of worship most acceptable to him, whoever admitted its truth, held every other mode of religion to be absurd and impious. Hence the zeal of the first converts to the Christian faith in propagating its doctrines, and the ardour with which they laboured to overturn every other form of worship. They employed, however, for this purpose, no methods but such as suited the nature of religion. By the force of powerful arguments, they convinced the understandings of men; by the charms of superior virtue, they allured and captivated their hearts. At length the civil power declared in favour of Christianity, and though numbers, imitating the example of their superiors, crowded into the church, many still adhered to their ancient superstitions. Enraged at their obliquity, the ministers of religion, whose zeal was still unabated, though their facility and virtue were much diminished, forgot so far the nature of their own mission, and of the arguments which they ought to have employed, that they armed the imperial power against these unhappy men; and as they could not persuade, they tried to compel them to believe.

"At the same time, controversies concerning articles of faith multiplied, from various causes, among Christians themselves; and the same unhallowed weapons which had first been used against the enemies of their religion were turned against each other. Every zealous disputant endeavoured to interest the civil magistrate in his cause, and each in his turn employed the secular arm to crush or to exterminate his opponents. Not long after, the bishops of Rome put in their claim to infallibility in explaining articles of faith, and deciding points in controversy; and, bold as the pretension was, they, by their artifices and perseverance, imposed on the credulity of mankind, and brought them to recognize it. To doubt or to deny any doctrine to which these unerring instructors had given the sanction of their approbation, was held to be not only a resisting of truth, but an act of rebellion against their sacred authority; and the secular power, of which, by various arts, they had acquired the absolute direction, was instantly employed to avenge both.

"Thus Europe had been accustomed, during many centuries, to see speculative opinions propagated or defended by force, the charity and mutual forbearance which Christianity recommends with so much warmth, were forgotten, the sacred rights of conscience and of private

Toleration
||
Tolufiera.

private judgment were unheard of; and not only the idea of toleration, but even the word itself, in the sense now affixed to it, was unknown. A right to extirpate error by force, was universally allowed to be the prerogative of those who possessed the knowledge of truth; and as each party of Christians believed they had got possession of this invaluable attainment, they all claimed, and exercised, as far as they were able, the rights which it was supposed to convey. The Roman Catholics, as their system rested on the decisions of an infallible judge, never doubted that truth was on their side, and openly called on the civil power to repel the impious and heretical innovators who had risen up against it. The Protestants, no less confident that their doctrine was well-founded, required with equal ardour the princes of their party to check such as presumed to impugn or oppose it. Luther, Calvin, Cranmer, Knox, the founders of the reformed church in their respective countries, inflicted, as far as they had power and opportunity, the same punishments which were denounced against their own disciples by the church of Rome, on such as called in question any article in their creeds. To their followers, and perhaps to their opponents, it would have appeared a symptom of diffidence in the goodness of their cause, or an acknowledgment that it was not well-founded, if they had not employed in its defence all those means which it was supposed truth had a right to employ.

“It was towards the close of the 17th century, before toleration, under its present form, was admitted first into the republic of the United Provinces, and from thence introduced into England. Long experience of the calamities of mutual persecution, the influence of free government, the light and humanity acquired by the progress of science, together with the prudence and authority of the civil magistrate, were all requisite in order to establish a regulation so repugnant to the ideas which all the different sects had adopted from mistaken conceptions concerning the nature of religion and the rights of truth.”

TOLOSA, a town of Spain, in the province of Biscay, and capital of Guipuscoa. It is not large, but it is the capital of the province. It is seated in a pleasant valley, between two rivers, Araxes and Oriz; over which there are two handsome bridges, and near them are several natural cascades. W. Long. 2. 3. N. Lat. 43. 12.

TOLU, a town of South America, in Terra Firma, and in the government of Carthagena; famous for the fine balsam of Tolu, brought into Europe from thence, and produced from a tree like a pine. It is seated on a bay of the north sea, 60 miles south of Carthagena. W. Long. 72. 55. N. Lat. 9. 40.

TOLUIFERA, the BALSAM OF TOLU TREE; a genus of the monogynia order, belonging to the decandria class of plants. There is but one species, growing naturally near Carthagena in America, from whence the late Dr Houstoun sent the seeds to England: in its native place this grows to a tree of a large size. The bark is very thick, rough, and of a brown colour; the branches spread out wide on every side, and are garnished with winged leaves, composed of several oblong lobes, placed alternately along the foot-stalk, terminated by an odd one, rounded at both ends, but run out to an acute point at the top; they are

Vol. X.

smooth, of a light-green colour, and sit close to the foot-stalk. The flowers are produced in small bunches at the wings of the branches, each standing upon a slender foot-stalk almost an inch long; their empalements are of the round bell-shape, being of one leaf, which is slightly scalloped at the brim into five obtuse parts. The flower has four narrow petals of a yellow colour, which are a little longer than the empalement, and one more whose tail is of the same length with the other petals; the top of it is of an oval heart-shape, stretched out beyond the other parts; it has ten short stamina within the tube of the flower, which are terminated by oblong erect summits, of a sulphur colour; and at the bottom of the tube is situated a roundish germen, having a very short style, crowned by an acute-pointed stigma. After the flower is past, the germen turns to a roundish fruit the size of a large pea, divided into four cells, each containing one oblong oval seed.—This tree may be propagated by seeds, which must be procured from the country where it grows naturally, and should be fresh, otherwise they will not grow. When they are gathered from the tree, they should be put up in sand to preserve them; for when they are sent over in papers, the insects generally devour them. These seeds must be sown in pots filled with light earth as soon as they arrive, and plunged into the tan. If it should happen in autumn or winter, they should be plunged into the stove; but in spring or summer, they may be plunged into the tan-bed under a frame; they should be taken out of their covers, otherwise they will be long in the ground before they vegetate. When the plants come up, and are fit to remove, they should be carefully transplanted, each into a separate pot, and plunged into a good hot-bed of tanners bark, shading them from the sun till they have taken new root; after which they should be treated in the same way as the coffee-tree, with which management the plants will succeed.

TOMPION, a sort of bung or cork used to stop the mouth of a cannon. At sea this is carefully encircled with tallow or putty, to prevent the penetration of the water into the bore, whereby the powder contained in the chamber might be damaged or rendered incapable of service.

TON, a measure or weight. See TUN.

STONE, or TUNE, in music, has several senses.

1. It is most immediately taken for that interval which characterizes the diatonic system or species, or what, in our language, we call a note played or sung. In this acceptance there are two kinds of tones; viz. the *major tone*, whose proportion is as 8 to 9, and which results from the difference between the fourth and the fifth; and the *minor tone*, whose proportion is as 9 to 10, and which results from the difference between the third minor and the fourth.—The production of the major and that of the minor tone, are equally found beginning with *ut* at the second *re*, which forms a fifth above *sol*: for the quantity by which this *re* is superior to the octave of the first *ut*, is exactly in the proportion of 8 to 9; and that by which the same *re* is inferior to *mi*, the third major of that octave, is in the proportion of 9 to 10.

2. That degree of elevation which is taken by voices or instruments for performing a piece of music, is likewise called the *tone* or *pitch*. It is in this sense that

Tolufiera
||
Tone.

Tone.

we say, in a concert, the *tone* is too high or too low.

3. Tone is taken for a rule of modulation with relation to a fundamental note or principal sound, which is called the *tonic* or *key note*. See Tonic.

With respect to the tones of the ancients, may be consulted Rousſeau's Dictionary, at the word *Mons*.

As our modern ſyſtem contains in each octave 12 different notes or ſounds, which, relatively to that octave, are called *ſemi-tones*; each of theſe ſounds may ſerve for the fundamental of a tone, that is to ſay, may be its tonic. Theſe tones are already 12; but as the major and minor modes are applicable to each of them, upon theſe 12 there are 24 different modulations of which our muſic is ſuſceptible. See MODULATION.

Theſe tones differ one from another by various degrees of elevation between the loweſt and higheſt, according as the tonic takes its ſtation. They differ alſo by the different alteration of ſounds and intervals produced in each tone by the temperament; ſo that, upon a harpſichord properly in tune, a practiſed ear recognizes any tone whatever whole modulation it hears; and theſe tones are equally recognized upon harpſichords, though tuned higher or lower ſome than others: which ſhows, that this diſcernment proceeds at leaſt as much upon the modification which every note receives from the whole chord, as upon the degree of elevation which the tonic occupies in the harpſichord.

From hence ariſes a ſucceſſion of varieties and beauties in modulation. From hence ariſes a wonderful diverſity and energy in the expreſſion. From hence ariſes, in ſhort, the power of exciting different feelings by ſimilar chords, when ſtruck in different tones. Would you produce the majeſtic, the grave? The *F ut fa*, and the major tones eſtuated by a flat, will expreſs it nobly. Would you produce the gay and the cheerful? Take *A mi la*, *D la re*, the major tones eſtuated by a ſharp. Would you produce ſuch ſtrains as are moving and tender? Take the minor tones eſtuated by a flat. *C ſol ut* minor, inſpire the ſoul with tendernels; *F ut fa* minor, carry it even to melancholy and grief. In a word, every tone, every mode, has its peculiar expreſſion, which ought to be known and perceived with delicacy; and this is one of the means which render a compoſer of art and genius in ſome degree maſter of the affections of thoſe who hear him. It is, however, a kind of ſuccedaneum to the ancient modes, though far from reaching their expreſſion or energy.

Yet it is this rich and agreeable diverſity of which (ſays Rousſeau) M. Rameau would deprive muſic, in wholly reducing every mode to one inſipidly equal and monotonous harmony, by his rule for temperament, though it had been ſo often propoſed and neglected before him. According to this author, the whole harmony would be more perfect by its obſervation. It is nevertheless abſolutely certain, that nothing can be gained by this on one hand, without loſing its equivalent on the other; and though we ſhould grant (what is by no means true) that by this temperament the harmony in general would be rendered more pure, would this compenſate what we loſe in point of expreſſion? See TEMPERAMENT.

To what has been already ſaid by M. Rousſeau, we muſt beg leave to add two obſervations. 1. The eſſence of the tone conſiſts in this, that by it the ſeries

of diatonic intervals immediately riſing or deſcending, whether major or minor, is regulated and known from any fundamental note which we aſſume. Tone, therefore, is the conſtitution of the octave, as determined by that fundamental note. The fundamental note itſelf is the key. Hence the *tone* differs from the *mode*, as the former regulates the nature and ſucceſſion of intervals contained in the octave; the latter modifies all the chords whether natural or artificial, particularly the third and fifth. 2. M. D'Alembert, in the ſecond edition of his Elements, (ſee the article *Muſic*, n° 72. note *u*) has conſidered at ſome length, and with ſome degree of accuracy, the advantages and inconveniences reſulting from temperament. He ſeems fairly to have ſtated the objections of muſicians againſt it. He aſſerts, that without it, in paſſing from one mode to another, the ear is ſhocked; and agrees with M. Rameau, that the character of different harmonies does not ariſe from any differences in the intervals of the diatonic ſcale, but from the ingenious and agreeable intertexture of the modes, and from other circumſtances enumerated in the note. He adds, that from all which has been ſaid in his work concerning the formation of the diatonic ſcale, and that ſpecies of muſic which it characterizes, it muſt appear to be the obvious intention of nature, that the intervals in that ſyſtem, whether major or minor, whether conſiſting of a ſemi-tone or a full note, ſhould each of them be exactly ſimilar one to another, which cannot be effected without having recourſe to temperament.

TONGUE, in anatomy. See there n° 366, *d* and 403.

TONIC, in muſic, ſignifies a certain degree of tenſion, or the ſound produced by a vocal ſtring in a given degree of tenſion, or by any ſonorous body when put in vibration. It has already been obſerved in other articles, that the word *tone* ſignifies the natural ſeries or ſucceſſion of the diatonic ſcale, whether major or minor, or conſiſting in intervals of both kinds, commencing from any particular note. The tonic therefore, or key, is the ſound from whence that ſeries commences; and it is ſo called, becauſe it eſtabliſhes the nature of the ſeries, and, as it were, opens a paſſage to it. With this every piece of muſic, whether in harmony or melody, for the moſt part begins, at leaſt when the excluded notes are ſuſhied. By excluded notes we mean thoſe notes which are ſeparated from the air by a bar, yet which do not conſtitute a bar; becauſe they are parts of a time, the reſt of which is ſuppoſed to have paſſed before the commencement of the air; and for which, at the end of the ſtrain, there is, or ought to be, always an interval in duration left unoccupied.

Here then we have ſaid, that the air commences ſor the moſt part with its tonic or key; that it ſhould end with the ſame note, is a rule more generally obſerved, and more neceſſary to be obſerved; but that its baſis ſhould end upon the tonic, is indiſpenſable. Whatever kind of third the key or tonic has above it, determines the mode. If the third be major, ſuch likewiſe is the mode; if minor, the mode is alſo minor. Thus, upon every tonic or key, we may compoſe in either mode. In ſhort, muſicians recognize this peculiarity in the tonic, that the perfect chord does not rigorouſly belong to any other note except itſelf. When that chord is ſtruck upon another note, either ſome diſſonance

Tone-
it
Tonic.

Tonic
||
Tonquin.

nance is underfoot, or some other note becomes the key for that instant.

By this method of transposition, the tonic or key bears the name of *C* or *at* in the major mode, and of *A* or *la* in the minor. See Music, Chap. XII.

Tonic, says Rousseau, is likewise the name given by Aristoxenus to one of the three kinds of chromatic music whose divisions he explains, and which was the ordinary chromatic of the Greeks, proceeding by two semi-tones in succession, and afterwards a third minor.

Tonic Dominant. See DOMINANT.

TONNAGE and POUNDAGE, an ancient duty on wine and other goods. The origin of tonnage and poundage seems to have been this. About the 21st of Edward III. complaint was made that merchants were robbed and murdered on the seas. The king thereupon, with the consent of the peers, levied a duty of 2s. on every ton of wine, and 6d. in the pound on all goods imported; which was treated as illegal by the commons. About 25 years after, the king, when the knights of shires were returned home, obtained a like grant from the citizens and burghes, and the year after it was regularly granted in parliament. These duties were diminished sometimes, and sometimes increased; at length they seem to have been fixed at 3s. tonnage and 1s. poundage. In old times these were distinguished from customs, which were considered as duties on staple commodities, though they have been long since blended together. The fixing of staple towns had its advantages and disadvantages; and even the great staple at Calais, which rendered the loss of that place so much regretted, cramped our navigation. By successive acts of the legislature, the liberty and property of the subjects of all ranks being better secured, promoted domestic industry, and thereby the welfare and happiness of the people.

TONQUIN, a kingdom of Asia, in the East Indies, beyond the Ganges; bounded on the north by the province of Yunnan in China, on the east by the province of Canton and the bay of Tonquin, on the south by Cochinchina, and on the west by the kingdom of Laos. It is about 1200 miles in length, and 500 in breadth; and is one of the finest and most considerable kingdoms of the East, as well on account of the number of inhabitants, as the riches it contains and the trade it carries on. The country is thick set with villages; and the natives in general are of a middle stature and clean-limbed, with a tawny complexion. Their faces are oval and flatfish, and their noses and lips well proportioned. Their hair is black, long, lank, and coarse; and they let it hang down their shoulders. They are generally dexterous, nimble, active, and ingenious in mechanic arts. The weave a multitude of fine silks, and make curious lacker-works, which are transported to other countries. There is such a number of people, that many want employment; for they seldom go to work but when foreign ships arrive. The money and goods brought hither by the English and Dutch put them in action, for they have not money of their own sufficient to employ themselves; and therefore one-third at least, must be advanced beforehand by the merchants: and the ships must stay here till the goods are finished, which is generally five or six months. They are so addicted to gaming, that when every thing else is lost, they will stake their wives and children.

Tonquin.
Tonils

The garments of the Tonquinese are made either of silk or cotton; but the poor people and soldiers wear only cotton of a dark tawny colour. Their houses are small and low; and the walls either of mud, or hurdles daubed over with clay. They have only a ground-floor, with two or three partitions; and each room has a square hole to let in the light. The villages consist of 30 or 40 houses, surrounded with trees; and in some places there are banks to keep the water from overflowing their gardens, where they have oranges, betels, melons, and salad-herbs. In the rainy season they cannot pass from one house to another without wading through the water: they sometimes have boats. In the capital city called *Cacho*, there are about 20,000 houses, with mud-walls, and covered with thatch; a few are built with brick, and roofed with pan-tiles. In each yard is a small arched building like an oven, about six feet high, made of brick, which serves to secure their goods in case of fire. The principal streets are very wide, and paved with small stones. The king of Tonquin has three palaces in it, such as they are; and near them are stables for his horses and elephants. The house of the English factory is seated at the north end of the city, fronting the river; and is the best in the city. The people in general are courteous, and civil to strangers; but the great men are proud, haughty, and ambitious; the soldiers insolent, and the poor thieves. They buy all their wives, of which the great men have several; but the poor are stinted for want of money. In hard times the men will sell both their wives and children, to buy rice to maintain themselves. The women offer themselves to strangers as wives, while they stay, and agree with them for a certain price. Even the great men will offer their daughters to the merchants and officers who are likely to stay six months in the country. They are not afraid of being with child; for if they are girls, they can sell them well when they are young, because they are fairer than the other inhabitants. These women are said to be very faithful; and are trusted with money and goods by the Europeans during their absence; and will make great advantage with them. The first new moon in the year that happens after the middle of January, is a great festival; when they rejoice for 10 or 12 days together, and spend their time in all manner of sports. Their common drink is tea, but they make themselves merry with arrack. The language is spoken very much in the throat; and some of the words are pronounced through the teeth, and has a great resemblance to the Chinese. They have several mechanic arts or trades; such as smiths, carpenters, joiners, turners, weavers, taylor, potters, painters, money-changers, paper-makers, workers in lacker, and bell-founders. Their commodities are gold, musk, silks, calicoes, drugs of many sorts, woods for dyeing, lacquered wares, earthen wares, salt, aniseeds, and worm-seeds. The lacquered ware is not inferior to that of Japan, which is accounted the best in the world. With all these merchandises, one would expect the people to be very rich, but they are in general very poor; the chief trade being carried on by the Chinese, English, and Dutch. The goods imported, besides silver, are salt-petre, sulphur, English broad cloth, pepper, spices, and great guns.

TONSILS, in anatomy. See there n° 366, p. 43 H 2 TON,

Tonfure

||
Top.

TONSURE, in ecclesiastical history, a particular manner of shaving or clipping the hair of ecclesiastics or monks. The ancient tonsure of the clergy was nothing more than polling the head, and cutting the hair to a moderate degree, for the sake of decency and gravity: and the same observation is true with respect to the tonsure of the ancient monks. But the Romans have carried the affair of tonsure much farther; the candidate for it kneeling before the bishop, who cuts the hair in five different parts of the head, *viz.* before, behind, on each side, and on the crown.

TOOL, among mechanics, denotes in general any small instrument used as well for making other complex instruments and machines, as in most other operations in the mechanic arts.

TOOTH, in anatomy. See there, n° 26.

TOOTHACH. See *MEDICINE*, n° 621, 622, and *ELECTRICITY*, parag. ult.

TOOTHACH Tree. See *XANTHOXYLUM*.

TOP, a sort of platform, surrounding the lower mast-head, from which it projects on all sides like a scaffold.

The principal intention of the top is to extend the top-mast shrouds, so as to form a greater angle with the mast, and thereby give additional support to the latter. It is sustained by certain timbers fixed across the hounds or shoulders of the mast, and called the *treble-trees* and *cross-trees*.

Besides the use above-mentioned, the top is otherwise extremely convenient to contain the materials necessary for extending the small sails, and for fixing or repairing the rigging and machinery with more facility and expedition. In ships of war it is used as a kind of redoubt, and is accordingly fortified for attack or defence; being furnished with swivels, musketry, and other fire-arms, and guarded by a thick fence of corded hammocks. Finally, it is employed as a place for looking out, either in the day or night.

The frame of the top is either close-planked like a platform, or open like a grating. The former kind is generally stronger and more convenient; but the latter is much better in tempestuous weather, as presenting a smaller surface to the wind when the ship leans over to one side, and by consequence being less exposed to its efforts.

In all ships of war, and in the largest merchantmen, the top is fenced on the aft-side by a rail of about three feet high, stretching across, and supported by stanchions, between which a netting is usually constructed. The outside of this netting is generally covered with red baize or red painted canvas, which is extended from the rail down to the edge of the top, and called the *top-armour*. By this name it seems to have been considered as a sort of blind, behind which the men may conceal themselves from the aims of the enemy's fire-arms in time of action, whilst they are charging their own muskets, carabines, or swivels.

Top-Mast, the second division of a mast; or that part which stands between the upper and lower pieces. See the article *MAST*.

Top Sails, certain large sails extended across the top-masts by the topail-yard above, and by the yard attached to the lower mast beneath; being fastened to the former by robands, and to the latter by means of two great blocks fixed on its extremities, thro' which

the topail-sheets are inserted, passing from thence to two other blocks fixed on the inner part of the yard close by the mast: and from these latter the sheets lead downwards to the deck, where they may be slackened or extended at pleasure. See the article *SAIL*.

TOPAZ, in natural history, a gem called by the ancients *chrysolite*, as being of a gold colour.

The topaz, when perfect and free from blemishes, is a very beautiful and valuable gem; it is, however, very rare in this state. It is of the number of those gems which are found only in the round or pebble form, there never having been yet seen a true and genuine topaz of a columnar figure, though the far greater part of what our jewellers call such are in that form. The greatest part of the true topazes are no larger than grains of a coarse seed; among these there are, however, some met with of the size of a pea, and some much larger, though these are very rare. It is of a roundish or oblong figure in its native or rough state, and usually is flatted on one side; and is generally of a bright and naturally polished surface, tolerably transparent. They are ever of a fine yellow colour; but they have this, like the other gems, in several different degrees: the finest of all are of a true and perfect gold colour; but there are some much deeper, and others extremely pale, so as to appear scarce tinged. The oriental topaz is equal to the ruby in hardness, and is second only to the diamond in lustre. The topazes of the other parts of the world fall off greatly from this hardness; but the purest of the genuine ones are considerably harder than crystal. The topaz on being thrown into a charcoal fire entirely loses its colour; and when taken out, is a very fine colourless stone, undistinguishable from that known by the name of the *white sapphire*. Upon the whole it appears, that the oriental-coloured gems are much alike in their matter, differing scarce at all, except in colour; and that when they are found either naturally colourless, or rendered so by art, it is not easy to distinguish one of them from the other.

The finest topazes in the world are found in the East Indies; but they are very rare there of any great size: the Great Mogul, however, at this time, possesses one which is said to weigh 157 carats, and to be worth more than 20,000 pounds. The topazes of Peru come next after these, in beauty and in value. The European are principally found in Silesia and Bohemia, and are generally full of cracks and flaws, and of a brownish yellow.

Besides all these degrees of value in the genuine topazes, our jewellers keep what they call a kind of them, inferior greatly to the true ones; all these are common hexangular crystals, coloured to a paler or deeper yellow in mines: these they cut into stones for rings, and sell under the name of *topazes*; and most of the stones we see under that name are such.

TOPHUS, in medicine, denotes a chalky or stony concretion in any part of the body; as the bladder, kidney, &c. but especially in the joints.

TOPIC, a general head, or subject of discourse.

TOPICS, in oratory. See *ORATORY*, n° 2—23.

TOPICS, or *Topical Medicines*, are the same with external ones, or those applied outwardly to some diseased and painful part: such are plasters, cataplasms, unguents, &c.

Topaz

Topics.

TOPOGRAPHY, a description or draught of some particular place, or small track of land, as that of a city or town, manor or tenement, field, garden, house, castle, or the like; such as surveyors set out in their plots, or make draughts of, for the information and satisfaction of the proprietors.

TOPSHAM, a town of Devonshire, in England, seated on the river Exmouth, five miles south-east of Exeter, to which place the river was formerly navigable; but in time of war was choked up undesignedly, so that ships are now obliged to load and unload at Topsham. W. Long. 3. 40. N. Lat. 50. 37.

TOR, a town of Asia, in Arabia Petrea, seated on the Red Sea, with a good harbour defended by a castle. There is a handsome Greek convent, in whose garden are fountains of bitter water, which they pretend are those rendered sweet by Moses by throwing a piece of wood into them. Some think that this town is the ancient Elana. E. Long. 31. 25. N. Lat. 28. 0.

TORBAY, a fine bay of the English channel, on the coast of Devonshire, a little to the east of Dartmouth, formed by two capes, called *Bury Points*, and *Bob's Nose*.

TORIES, in the history of England, a faction or party opposed to the whigs. See **WHIGS**.—The Tories are great sticklers for the prerogatives of the crown, as the whigs are for the liberties and privileges of the people: though, in truth, the principles of the moderate people of both parties do not greatly differ.

TORMENTILLA, **TORMENTIL**; a genus of the polygynia order, belonging to the iconfandria class of plants. There are two species, the most remarkable of which is the erecta, growing very frequently in barren pastures, moors, and heaths, in Scotland, England, and the neighbouring islands. The roots consist of thick tubercles, an inch or more in diameter, replete with a red juice, of an astringent quality. They are used in most of the Western Isles, and in the Orkneys, for tanning of leather; in which intention they are proved by some late experiments to be superior even to the oak-bark. They are first of all boiled in water, and the leather is afterwards steeped in the liquor. In the islands of Tirey and Col the inhabitants have destroyed so much ground by digging them up, that they have lately been prohibited the use of them. A decoction of these roots in milk is also frequently administered by the inhabitants of the same islands in diarrhoeas and dysenteries, with good success; but perhaps it would be most proper not to give it in dysenteries till the morbid matter be first evacuated. A spirituous extract of the plant stands recommended in the sea-scurvy, to strengthen the gums and loosen the teeth. Linnaeus informs us, that the Laplanders paint their leather of a red colour with the juice of the roots.

TORNADO, a sudden and vehement gulf of wind from all points of the compass, frequent on the coast of Guinea.

TORNE, the capital of Torne Lapmark, a province of Sweden, situated at the mouth of the river Torne, at the bottom of the Bothnic Gulph, upon a little island made by the river, 400 miles north of Stockholm. E. Long. 22. 45. N. Lat. 65. 45.

TORPEDO, the **CRAMP-FISH**. See **RAJA**.

The surprising property of this fish in giving a violent shock to the person who takes it in his hands, or

who tread upon it, was long an object of wonder. Torpedo. For some time it was in general reckoned to be entirely fabulous; but at last the matter of fact being ascertained beyond a doubt, philosophers endeavoured to find out the cause. M. Reaumur resolved it into the action of a vast number of minute muscles, which by their accumulated force gave a sudden and violent stroke to the person who touched it. But solutions of this kind were quite unsatisfactory, because the stroke was found to be communicated through water, iron, wood, &c. When the phenomena of electricity began to be better known, it was then suspected that the shock of the torpedo was occasioned by a certain action of the electric fluid; but as not the least spark of fire, or noise, could ever be perceived, this too seemed insufficient. Of late, however, Mr Walfsh has with indefatigable pains, not only explained this surprising phenomenon on the known principles of electricity, but given a demonstration of his being in the right, by constructing an artificial torpedo, by which a shock resembling that of the natural one can be given.

The electric organs of the torpedo consist of two sets of very small cylinders lying under the skin, one of which is electrified positively and the other negatively, seemingly at the pleasure of the fish. When a communication is made between the set of cylinders positively electrified, and those which are negatively so, a discharge and shock ensue, like what happens in the case of the Leyden vial. The only difficulty now is to account for the total absence of a spark, (which in the case of the torpedo never exists even in the smallest degree,) and the impossibility of conducting the shock through the smallest interval of air. But this also is explained in a satisfactory manner by Mr Walfsh, and shown to be nothing else than what every day takes place in our electrical experiments. It is well known, that a small charge of electricity, if put into a little vial, will occasion a bright spark and loud noise when discharged. But if the same charge is put into a vial much larger, the spark and noise will be less in proportion; neither will the spark break through near such a space of air in the latter case as in the former; though the shock would in both cases be the same to a person who received it through his body. If, instead of a large vial, we suppose the charge to be diffused all over a large battery, the shock would still be the same, and yet the spark and noise attending it would be almost imperceptible. The case is just the same with the torpedo. Each of the electric organs is a battery composed of innumerable small cylinders, which discharging themselves all at once produce a formidable shock; but by reason of the smallness of the charge of each, the spark is imperceptible, and cannot break through the smallest space of air. The truth of this was exemplified in Mr Walfsh's artificial torpedo, which though it would give a very considerable shock through a conductor totally uninterrupted, yet on the least breach therein, even for the breadth of a hair, no shock was felt.

In every other respect the electricity of the torpedo agrees with that exhibited by the common electrical machines. An insulated person cannot receive a shock by touching one of the electric organs of the fish; but a violent stroke is given to the person, whether insulated or not, who lays one hand on the positive and the

Torpor
||
Tordc.

the other on the negative organ. The fish, as is reasonable to imagine, seems to have this electric property in its own power; and appears sensible of his giving the shock, which is accompanied by a kind of winking of his eyes.

TORPOR, a numbness, or defect of feeling and motion. Galen says it is a sort of intermediate disorder between palsy and health.

TORREFACTION, in chemistry, is the roasting or scorching of a body by the fire, in order to discharge a part either unnecessary or hurtful in another operation. Sulphur is thus discharged from an ore before it can be wrought to advantage.

TORRENT, denotes a temporary stream of water falling suddenly from mountains, whereon there have been great rains, or an extraordinary thaw of snow.

TORRENTIUS (John), a painter of Amsterdam, born at Haerlem in 1589, who excelled in representing objects of still life, and sometimes painted conversations which were admired for a lovely tone of colouring. While he practised in this manner, he lived in general esteem and affluence; but, unhappily, he grew abandoned in his morals, and equally so in his style of painting, prostituting a delicate pencil to the most obscene and depraved purposes. At last, by instituting a secret society of Adamites, he attracted the notice of the magistrates, who brought him to trial; and as he denied his own performances, and any connection with his detestable assembly, he was condemned to the torture, his lewd pictures were burned by the common executioner, and he was sentenced to the house of correction for 20 years. He supported the torture with incredible obliquity; and after some time of confinement, being released at the request of the English ambassador, he went to London, where he resided for a few years. But the English, who detested his profligacy more than they admired his art, discountenanced him so much that he retired to Amsterdam, where he died in obscurity and contempt in 1640.

TORRICELLI (Evangeliste), an illustrious Italian mathematician and philosopher, born at Faenza in 1608. He was trained in Latin literature by his uncle a monk; and after cultivating mathematical knowledge for some time without a master, he studied it under father Benedict Castelli, professor of mathematics at Rome. Having read Galileo's dialogues, he composed a treatise on motion, on his principles, which brought him acquainted with Galileo, who took him home as an assistant: but Galileo died in three months after. He became professor of mathematics at Florence, and greatly improved the art of making telescopes and microscopes: but he is best known for finding out a method of ascertaining the weight of the atmosphere by quicksilver; the barometer being called, from him, the *Torricellian tube*. He published *Opera Geometrica*, 4to, 1644; and died in 1647.

TORRICELLIAN EXPERIMENT, a famous experiment made by Torricelli, a disciple of the great Galileo, by which he demonstrated the pressure of the atmosphere in opposition to the doctrines of suction, &c. finding that pressure able to support only a certain length of mercury, or any other fluid, in an inverted glass tube. See **BAROMETER**.

TORSK, or **TUSK**, in ichthyology. See **GADUS**.

TORTOISE, in zoology. See **TESTUDO**.

TORTOISE-SHELL. The upper shell of the tortoise is composed of two dissimilar substances: that which immediately invests the back of the animal is of the bony kind, and almost as hard as stone; the outer lamina is horny, flexible, here and there transparent. It is only this last that is called *tortoise-shell*, and in which the beautiful colours and variegations reside. The horny shell consists of several pieces, whose seams and junctures with one another, and with the bony part underneath, are sufficiently distinguishable. The workmen split them asunder by certain instruments, and employ the elegant horn for a variety of toys and utensils, combs, sword-hilts, clock-cases, boxes, coverings for musical instruments, perspective-glasses, &c. &c.

Working and joining of TORTOISE-SHELL—Tortoise-shell and horn become soft in a moderate heat, as that of boiling water, so as to be pressed, in a mould, into any form, the shell or horn being previously cut into plates of a proper size.

Plumier informs us, in his *Art de tourner*, that two plates are likewise united into one by heating and pressing them; the edges being thoroughly cleaned, and made to fit close to one another. The tortoise-shell is conveniently heated for this purpose by applying a hot iron above and beneath the juncture, with the interposition of a wet cloth to prevent the shell from being scorched by the irons: these irons should be pretty thick, that they may not lose their heat before the union is effected.

Both tortoise-shell and horns may be stained of a variety of colours, by means of the colouring drugs commonly used in dyeing, and by certain metallic solutions.

TORTURE, a grievous pain inflicted on criminals to make them confess the truth. See **RACK**.—The statute-law of England doth very seldom, and the common law doth never, inflict any punishment extending to life or limb, unless upon the highest necessity.

But note—on an indictment for high-treason, or for the lowest species of felony, viz. petit larceny, and in all misdemeanors, standing mute is equivalent to conviction. But upon appeals or indictment for other felonies or petit treason, the prisoner shall not be looked upon as convicted, so as to receive judgment for the felony; but shall, for his obliquity, receive the terrible sentence of penance, or *peine forte & dure*. See **ARRAIGNMENT**, and *PEINE forte & dure*.

The rack, or question, to extort a confession from criminals is a practice of a different nature: this being only used to compel a man to put himself upon his trial; that being a species of trial in itself. And the trial by rack is utterly unknown to the law of England. No person is to be subject to torture in Scotland, 7 Ann. c. 21.

TORUS, in architecture, a large round moulding used in the bases of columns. See **PLATE XXIX. fig. 3.**

TOUCAN, in ichthyology. See **RHAMPHASTOS**.

TOUCH-NEEDLE, among assayers, refiners, &c. little bars of gold, silver, and copper, combined together in all the different proportions and degrees of mixture; the use of which is to discover the degree of purity of any piece of gold or silver, by comparing the

Tortoise.
||
Touch.

the mark it leaves on the touchſtone with thoſe of the bars.

The metals uſually tried by the touchſtone are gold, ſilver, and copper, either pure, or mixed with one another in different degrees and proportions, by fuſion. In order to find out the purity or quantity of baſer metal in theſe various admixtures, when they are to be examined they are compared with theſe needles, which are mixed in a known proportion, and prepared for this uſe. The metals of theſe needles, both pure and mixed, are all made into laminæ or plates, one-twelfth of an inch broad, and of a fourth part of their breadth in thickneſs, and an inch and half long; theſe being thus prepared, you are to engrave on each a mark indicating its purity, or the nature and quantity of the admixture in it.

The black rough marbles, the baſaltes, or the ſofter kinds of black pebbles, are the moſt proper for touchſtones.

Now the method of uſing the needles and ſtone is this: The piece of metal to be tried ought firſt to be wiped well with a clean towel or piece of ſoft leather, that you may the better ſee its true colour; for from this alone an experienced perſon will, in ſome degree, judge beforehand what the principal metal is, and how and with what debaſed.

Then chooſe a convenient, not over large, part of the ſurface of the metal, and rub it ſeveral times very hardily and ſtrongly againſt the touchſtone, that in caſe a deceitful coat or cruſt ſhould have been laid upon it, it may be worn off by that friction: this, however, is more readily done by a grindſtone or ſmall file. Then wipe a flat and very clean part of the touchſtone, and rub againſt it, over and over, the juſt mentioned part of the ſurface of the piece of metal, till you have, on the flat ſurface of the ſtone, a thin metallic cruſt, an inch long and about an eighth of an inch broad: this done, look out the needle that ſeems moſt like to the metal under trial, wipe the lower part of this needle very clean, and then rub it againſt the touchſtone, as you did the metal, by the ſide of the other line, and in a direction parallel to it.

When this is done, if you find no difference between the colours of the two marks made by your needle and the metal under trial, you may with great probability pronounce that metal and your needle to be of the ſame alloy, which is immediately known by the mark engraved on your needle. But if you find a difference between the colour of the mark given by the metal, and that by the needle you have tried, chooſe out another needle, either of a darker or lighter colour than the former, as the difference of the tinge on the touchſtone directs; and by one or more trials of this kind you will be able to determine which of your needles the metal answers, and thence what alloy it is of, by the mark of the needle; or elſe you will find that the alloy is extraordinary, and not to be determined by the comparison of your needles.

TOUCHWOOD. See BOLETUS.

TOULON, an ancient, ſtrong, rich, and populous city of France, with a famous harbour, well covered from the north winds; and a biſhop's ſee. It is the principal town for naval ſtores on the Mediterranean ſea, and is fortified with ſtrong walls defended with baſtions. It has two moles, each ſeven hundred paces

in length, which almoſt ſurround the harbour, and leave but a narrow entrance for ſhips. There are always men of war here, as well as other ſhips; and there is a very fine quay paved with bricks. Near the arſenal, on the ſide of the quay, are magazines full of naval ſtores. The cathedral is remarkable for its high altar, and two fine chapels on each ſide, where there are ſeveral ſilver ſhrines ſet with precious ſtones. There are ſeveral other churches and convents; and a ſchool for officers, where they are taught every thing that regards the land or ſea ſervice. The harbour is defended by ſeveral forts, and is one of the beſt in Europe. E. Long. 6. 2. N. Lat. 43. 7.

TOULOUSE, one of the principal cities of France, in Upper Languedoc, and capital of the whole province, with an archbiſhop's ſee, a famous univerſity, a parliament, a mint, and an academy of belles lettres. It is ſeated on the river Garonne, which divides it into two unequal parts, that communicate by a large ſtone-bridge. It is very large, but is not peopled in proportion to its extent. The ſtreets are very handſome, and the walls of the city, as well as the houſes, are built with brick. The metropolitan church ſtands in a large ſquare, adorned with a fountain. It has ſeveral fine chapels, and the choir is very magnificent. There are ſeveral other churches and convents, too numerous to mention in particular. The town-houſe, which they call the *Capital*, is very magnificent. It is a place of ſome trade, and is ſeated at the end of the canal of Languedoc. E. Long. 1. 30. N. Lat. 42. 36.

TOUR (Henry de la), viſcount Turenne, a celebrated French general, was the ſecond ſon of Henry de la Tour duke of Bouillon, and was born at Sedan in 1611. He made his firſt campaigns in Holland under Maurice and Frederic Henry princes of Orange, who were his uncles by the mother's ſide; and even then diſtinguiſhed himſelf by his bravery. In 1634 he marched with his regiment into Lorraine; and having contributed to the taking of La Mothe, was, though very young, made mareſchal de camp. In 1636 he took Savre, and the year following the caſtles of Hirſon and Sorle; on which occaſion he performed an action like that of Scipio's, with reſpect to a very beautiful woman whom he ſent back to her husband. The viſcount Turenne continued to diſtinguiſh himſelf in ſeveral ſieges and battles, and in 1644 was made marſhal of France; but had the miſfortune to be defeated at the battle of Mariendal in 1645. However, he gained the battle of Nortlingen three months after; reſtored the elector of Treves to his dominions; and the following year made the famous junction of the French army with that of Sweden commanded by general Wrangel, which obliged the duke of Bavaria to demand a peace. Afterwards that duke breaking the treaty he had concluded with France, he was defeated by the viſcount Turenne at the battle of Zinnshausen, and in 1648 driven entirely out of his dominions. During the civil wars in France he ſided with the princes, and was defeated at the battle of Rhetel in 1650; but ſoon after was reſtored to the favour of the king, who in 1652 gave him the command of his army. He acquired great honour at the battles of Jerngau, Gien, and the ſuburbs of St Anthony, and by the retreat he made before the army commanded by

Touraine
Tournam-
ments.

the princes at Ville-Neuve St. George. In 1654 he made the Spaniards raise the siege of Arras: the next year he took Condé, St. Guilian, and several other places; gained the famous battle of Dunes; and made himself master of Dunkirk, Oudenarde, and almost all Flanders: this obliged the Spaniards to conclude the peace of the Pyrenees in 1660. These important services occasioned his being made marshal-general of the king's camps and armies. The war being renewed with Spain in 1667, Turenne commanded in Flanders; and took so many places, that in 1668 the Spaniards were obliged to sue for peace. He commanded the French army in the war against the Dutch in 1672; took 40 towns in 22 days; pursued the elector of Brandenburg even to Berlin; gained the battles of Slinthheim, Ladenburg, Enshiem, Mulhausen, and Turkeim; and obliged the Imperial army, which consisted of 70,000 men, to retrace the Rhine. By this campaign the viscount Turenne acquired immortal honour. He passed the Rhine to give battle to general Montecuculi, whom he followed as far as Saspach; but mounting upon an eminence to discover the enemy's camp, he was killed by a cannon-ball in 1675. All France regretted the loss of this great man, who by his military exploits had raised the admiration of Europe.

TOURAINNE, a province of France, bounded on the north by Maine, on the east by Orleansois, on the south by Berri, and on the west by Anjou and Poitou. It is about 58 miles in length, and 55 in breadth where it is broadest. This country is watered by 17 rivers, besides many brooks, which not only render it delightful, but keep up a communication with the neighbouring provinces. The air is temperate, and the soil is so fruitful, that it is called the *garden of France*. Tours is the capital town.

TOURNAY, a town of the Austrian Netherlands, in Flanders, and capital of a district called *Tournaysir*, with a bishop's see. It is divided into two parts by the river Scheld; and is large, populous, well built, and carries on a great trade in woollen stuffs and stockings. The cathedral is a very handsome structure, and contains a great many chapels with rich ornaments, and several magnificent tombs of marble and brass. The town was taken by the allies in 1709; but was ceded to the house of Austria by the treaty of Utrecht, tho' the Dutch had a right to put in a garrison. It was taken by the French in June 1745, who demolished the fortifications. E. Long. 3. 36. N. Lat. 50. 41.

TOURNAMENTS, in chivalry, were honourable exercises formerly used by all persons of note that desired to signalize themselves by their dexterity, &c. They were first instituted in Germany, according to historians, towards the beginning of the 10th century, and became afterwards a general practice: they derived their name from the French word *turner*, i. e. "to turn round," because to be expert in these exercises, much agility both of horse and man was requisite, they riding round a ring in imitation of the ancient Circi. They were the principal diversion of the 13th and 14th century.

The following account of English tournaments, extracted from Maitland's History of London, will not, it is hoped, be disagreeable to the reader.—In the reign of Edward IV. Roch, who was better known by the appellation of the *Bastard of Burgundy*, being

greatly celebrated for his acts of chivalry, came over and challenged the Lord Scales, brother to the queen, to fight with him; which Scales readily accepting, the king commanded lifts to be prepared in Smithfield (wherein to perform combat), of the length of 370 feet, and breadth of 260, with magnificent galleries for the reception of the illustrious spectators; where assembled the king, the nobility, and the principal gentry of both sexes. The first day they fought with spears, without a visible advantage on either side. The second they tourneyed on horseback, when the Lord Scales having a long pike fixed on his chaffron (pomel of his saddle), which as they closed, ran into the nostrils of the Bastard's horse, by the anguish whereof he reared himself with that violence, that he stumbled backwards, whereby his rider was unfortunately unhorsed: which occasioned him to cry out, "That he could not hold by the clouds;" and that though his horse had failed him, he would not fail to meet his adversary the next day. This being accordingly performed, they fought on foot with pole-axes; when Scales soon penetrating the Bastard's helmet, the king threw down his warder, whereupon they were immediately parted by the marshal. But the Bastard insinuating upon fighting out that weapon, a council was held to deliberate thereon. The result was, that if he persisted in renewing the combat, he must, according to the law of arms, be delivered to his adversary in the same condition he was in at his horse's misfortune: but rather than submit to those terms, he waved his pretension.

King Richard II. designing to hold a tournament at London on the Sunday after Michaelmas, sent divers heralds to make proclamations of it in all the principal courts of Europe; and accordingly not a few princes, and great numbers of the prime nobility, resorted hither from France, Germany, the Netherlands, &c. This solemnity began on Sunday afternoon, from the Tower of London, with a pompous cavalcade of 60 ladies, each leading an armed knight by a silver chain, being attended by their 'quires of honour, and, passing through Cheapside, rode to Smithfield, where the jousts and tournaments continued several days with magnificent variety of entertainments; on which occasion the king kept open house at the bishop of London's palace for all persons of distinction, and every night concluded with a ball.

Not long after this, three Scotch champions challenged three English to fight, which was performed in Smithfield with the greatest solemnity: the earl of Mar against the Lord Nottingham; Sir William Dorel the king of Scotland's banner-bearer, against Sir Pierce Courtney the king of England's standard-bearer; Cockburn, Esq; against Sir Nicholas Hawkirke. Mar and Cockburn were unhorsed; but the two standard-bearers were so well matched, that betwixt them it was a drawn battle. Voltaire, in his Essay upon the Civil Wars of France, p. 4, observes, that this romantic and dangerous sport was put an end to by the death of Henry II. king of France, who was killed at Paris in a tournament, which was the last in Europe.

TOURNEFORT (Joseph Pitton de), a famous French botanist, born at Aix in Provence in 1656. He had a passion for plants from his childhood, which overcame his father's views in putting him to study philo-

Tournam-
ments,
Tournam-
ments.

Tourniquet
Trachinus.

philosophy and divinity; therefore on his death he quitted theology, and gave himself up entirely to physics, natural history, and botany. He wandered over the mountains of Dauphine, Savoy, Catalonia, the Pyrenees, and the Alps, in search of new species of plants, which he acquired with much fatigue and danger. His fame in 1683 procured him the employment of botanic professor in the king's garden; and by the king's order, he travelled into Spain, Portugal, Holland, and England, where he made prodigious collections of plants. In 1700, Mr Tournesot, in obedience to another order, sailed over all the isles of the Archipelago, upon the coasts of the Black Sea, in Bithynia, Pontus, Cappadocia, Armenia, and Georgia; making observations on natural history at large, ancient and modern geography, religion, manners, and commerce. He spent three years in this learned voyage; and then resuming his profession, was made professor of physic in the college-royal. He died in consequence of an accidental crush of his breast by a cart-wheel, which brought on a spitting of blood and hydrothorax, that carried him off in 1708. He wrote Elements of Botany, both in French and Latin; A Relation of his Voyage into the Levant; with other pieces of less consideration.

TOURNIQUET, in surgery, an instrument formed with screws, for compressing any part with rollers, &c. for the stopping of hæmorrhages. See SURGERY, n° 407, *et seq.*

TOWER, a tall building consisting of several stories, usually of a round form, though some are square or polygonal. Towers are built for fortresses, prisons, &c. as the Tower of London, the Tower of the Bafilie, &c.

TOWN, a place inhabited by a considerable number of people, being of a middle size between a city and a village.

TOXICODENDRON, in botany. See RUUS.

TRACHEA, in anatomy. See there, n° 380.

TRACHINUS, the WEEVER, a genus of fishes belonging to the order of jugularis. There is but one species, viz. the draco, or common weever. The qualities of this fish were well known to the ancients, who take notice of them without any exaggeration: the wounds inflicted by its spines are exceedingly painful, attended with a violent burning and most pungent stinging, and sometimes with an inflammation that will extend from the arm to the shoulder.

It is a common notion that these symptoms proceed from something more than the small wound this fish is capable of inflicting; and that there is a venom infused into it, at least such as is made by the spines that form the first dorsal fin, which is dyed with black, and has a most suspicious aspect; though it is possible, that the malignity of the symptoms arises from the habit of body the person is in, or the part in which the wound is given. The remedy used by some fishermen is the sea-sand, with which they rub the place affected for a considerable time. At Scarborough, stale urine, warmed, is used with success. In the Universal Museum for November 1765, is an instance of a person who was reduced to great danger by a wound from this fish, and who was cured by the application of sweet oil, and taking opium and Venice treacle.

This fish buries itself in the sands, leaving only its

Vol. X.

nose out, and if trod on immediately strikes with great force; and they have been seen directing their blows with as much judgment as fighting cocks. Notwithstanding this noxious property of the spines, it is exceeding good meat.

The English name seems to have no meaning, being corrupted from the French, *la vive*, so called as being capable of living long out of the water, according to the interpretation of Belon. It grows to the length of 12 inches, but is commonly found much less. The irides are yellow: the under jaw is longer than the upper, and slopes very much towards the belly: the teeth are small. The back is straight, the sides are flat, the belly is prominent, the lateral line straight: the covers of the gills are armed with a very strong spine. The first dorsal fin consists of five very strong spines, which, as well as the intervening membranes, are tinged with black; this fin, when quiescent, is lodged in a small hollow. The second consists of several soft rays, commences just at the end of the first, and continues almost to the tail. The pectoral fins are broad and angular; the ventral fins small. The vent is placed remarkably forward, very near the throat: the anal fin extends to a small distance from the tail, is a little hollowed in the middle, but not so much as to be called forked. The sides are marked lengthwise with two or three dirty yellow lines, and transversely by numbers of small ones: the belly silvery.

TRACT, in geography, an extent of ground, or a portion of the earth's surface.

TRACT, in matters of literature, denotes a small treatise or written discourse upon any subject.

TRADE, in general, denotes the same with commerce, consisting in buying, selling, and exchanging of commodities, bills, money, &c. See COMMERCE, COIN, MONEY, COMPANY, &c.

TRADE-WINDS, denote certain regular winds at sea, blowing either constantly the same way, or alternately this way and that; thus called from their use in navigation, and the Indian commerce. See WIND.

TRADESCANT (John), an ingenious naturalist and antiquary, was, according to Anthony Wood, a Fleming or a Dutchman. We are informed by Parkinson, that he had travelled into most parts of Europe, and into Barbary; and from some emblems remaining upon his monument in Lambeth church-yard, it plainly appears that he had visited Greece, Egypt, and other eastern countries. In his travels he is supposed to have collected not only plants and seeds, but most of those curiosities of every sort which after his death were sold by his son to the famous Elias Ashmole, and deposited in his museum at Oxford. When he first settled in this kingdom cannot at this distance of time be ascertained. Perhaps it was at the latter end of the reign of queen Elizabeth, or the beginning of that of king James I. His print, engraven by Hollar before the year 1656, which represents him as a person very far advanced in years, seems to countenance this opinion. He lived in a great house at South Lambeth, where his museum was frequently visited by persons of rank, who became benefactors thereto: among these were king Charles I. (to whom he was gardener), Henrietta Maria his queen, archbishop Laud, George duke of Buckingham, Robert and William Cecil earls of Salisbury, and many other persons of distinction. John Tradescant may

Tradefcant therefore be juſtly conſidered as the earlieſt collector (in this kingdom) of every thing that was curious in natural hiſtory, viz. minerals, birds, fiſhes, inſects, &c. He had alſo a good collection of coins and medals of all forts, beſides a great variety of uncommon rarities. A catalogue of theſe, publiſhed by his ſon, contains an enumeration of the many plants, ſhrubs, trees, &c. growing in his garden, which was pretty extenſive. Some of theſe plants are, if not totally extinct, at leaſt become very uncommon, even at this time: though this able man by his great induſtry made it manifeſt, in the very infancy of botany, that there is ſcarce any plant extant in the known world that will not with proper care thrive in this kingdom.

When his houſe at South Lambeth, then called *Tradefcant's Ark*, came into Aſhmole's poſſeſſion, he added a noble room to it, and adorned the chimney with his arms, impaling thoſe of Sir William Dugdale, whoſe daughter was his third wife, where they remain to this day.

It were much to be wiſhed, that the lovers of botany has viſited this once famous garden, beſore, or at leaſt in the beginning of the preſent century. But this ſeems to have been totally neglected till the year 1749, when Dr Watſon and the late Dr Mitchell favoured Royal Society with the only account now extant of the remains of Tradefcant's garden.

When the death of John Tradefcant happened is not known; no mention being made thereof in the register-book of Lambeth church.

TRADITION, among eccleſiaſtical writers, denotes certain regulations concerning the rites, ceremonies, &c. of religion, which we ſuppoſe to have been handed down from the days of the apoſtles to the preſent time.

TRAGACANTH. See *Gum Tragacanth*.

TRAGEDY, a dramatic poem, repreſenting ſome final action performed by illuſtrious perſons, and which has frequently a fatal iſſue or end. See *POETRY*, Part. II. ſect. 1.

TRAGI-COMEDY, a dramatic piece, partaking both of the nature of tragedy and comedy; the event whereof is not bloody nor unhappy, and wherein is admitted a mixture of leſs ſerious characters.

TRAJAN (Marcus Ulpian), a celebrated Roman emperor, who gained many victories over the Parthians and Germans, puſhing the empire to its utmoſt extent on the eaſt and north ſides. He died at Silinunte, a city of Cilicia, which from him was called *Trajanopolis*, in the year 117.

TRAJAN'S Column, a famous hiſtorical column erected in Rome, in honour of the emperor Trajan. It is of the Tuſcan order, though ſomewhat irregular; its height is eight diameters, and its pedeaſt Corinthian: it was built in a large ſquare there called *Forum Romanum*. Its baſe conſiſts of 12 ſtones of an enormous ſize, and is raiſed on a ſocle, or foot, of eight ſteps: withinſide is a ſtair-caſe illuminated with 44 windows. It is 140 feet high, which is 35 feet ſhort of the Antonine column, but the workmanſhip of the former is much more valued. It is adorned from top to bottom with baſſo relievo, repreſenting the great actions of the emperor againſt the Dacians.

TRAJECTUS RHENI (anc. geog.), a town of Belgica; diſtant 15 miles by the Itinerary, but ſcarce fix,

from Mannaricum. Its name and ſituation ſhow it to be *Utrecht*, capital of the province of that name. E. Long. 5°, Lat. 52°, 7'. The appellation *Utrecht*, is from *Oud trecht*, the "old paſſage;" *Vetus Trajectus*, as it was called in Charlemagne's days; whence ſome barbarouſly form *Ultrajectum*; more elegantly called *Trajectus Rheni*, or *ad Rhenum*.

TRAIN, a line of gun-powder laid to give fire to a quantity thereof, in order to do execution by blowing up earth, works, buildings, &c.

TRAIN of Artillery, includes the great guns and other pieces of ordnance belonging to an army in the field.

TRAIN-Oil, the oil procured from the blubber of a whale by boiling.

TRALLIAN (Alexander), a Greek writer on phyſic, a native of Tralles in Lydia, who lived about the middle of the fixth century. His works are divided into 12 books, in which he treats of diſtempers as they occur, from head to foot; he was the firſt who opened the jugular vein, and that uſed cantharides as a bliſter for the gout. Dr Friend, in his *Hiſtory of Phyſic*, ſtyles him one of the moſt valuable authors ſince the time of Hippocrates. Though he appears on the whole to have been a rational phyſician, yet there are things in his writings that favour of enthuiſaſm and ſuperſtition.

TRALOS MONTES, a province of Portugal, called in Latin *Transmontana*; becauſe ſituated on the eaſt ſide of a chain of hills that ſeparate it from Entre Minho e Douro. It is bounded on the north by Galicia; on the ſouth by the provinces of Beira and Leon; by the laſt of which it is bounded alſo to the eaſt. Its length from north to ſouth is upwards of 120 miles, and its breadth about 80. It is full of mountains, and produces little corn, but plenty of wine, fruits of ſeveral forts, and abundance of game.

TRANSACTION, an accommodation of ſome buſineſs or diſpute between two parties by a mutual and voluntary agreement between them.

TRANSCENDENTAL, or TRANSCENDENT, ſomething elevated, or raiſed above other things; which paſſes and tranſcends the nature of other inferior things.

TRANSCRIPT, a copy of any original writing, particularly that of an act or inſtrument inſerted in the body of another.

TRANSFER, in commerce, an act whereby a perſon ſurrenders his right, intereſt, or property in any thing moveable or immoveable to another.

TRANSFORMATION, in general, denotes a change of form, or the aſſuming a new form different from a former one.

TRANSFUSION, the act of pouring a liquor out of one veſſel into another.

TRANSFUSION of Blood, an operation by which it was ſome time ago imagined that the age of animals would be renewed, and immortality, or the next thing to it, conferred on thoſe who had undergone it. The methods of performing it were as follow.

1. Take up the carotid artery of the dog, or other animal, whole blood is to be expended; ſeparate it from the nerve of the eighth pair, and lay it bare for above an inch. Then make a ſtrong ligature, not to be untied again, on the upper part of the artery; but

Transfusion an inch below, viz. towards the heart, make another

ligature with a running knot, which may be loosened or fastened as occasion requires. Having made these two knots, draw two threads under the artery, between the two ligatures; then open the artery, and put in a quill, or rather a crooked pipe of silver or brass, so slender that one end may enter a quill, and having at the other end, which is to go into the artery, a small knob. This being done, make fast the artery to the pipe by means of the two threads abovementioned, stopping the end of the quill with a peg till there be occasion for opening it. Perform a similar operation on the jugular vein of another dog; and having made a communication between the two animals, let another vein be opened in the animal into which the blood is to be transfused, and let the blood run freely out from it. The blood from the animal which is to be killed will run into the jugular vein, and supply the place of that which runs out from him; and thus the one dog will be bled to death, while the other suffers nothing, but will run about briskly as soon as he is unloosed and the wounds tied up.

2. In making this experiment, the following circumstances are to be attended to. 1. That the animals be fastened at such convenient distance from one another that the vein or artery be not stretched. 2. If the pulse fails beyond the quill in the jugular vein, the passage will be stopped up by coagulated blood, in which case the quill must be taken out and cleaned.

3. It must also be considered, that after a few minutes the blood of the emittent animal will mix with the other, and run out at the orifice; therefore, in order to be assured that the recipient animal has none of his own blood in him, two or three or more animals may be prepared, and all of them bled into one.

4. The most probable use of this experiment may be, that from several found animals a diseased one may be supplied with an entire new mass of blood, and that without destroying or hurting in the least the animals which give it; as an healthy animal could at any time spare a pretty large quantity of blood without any apparent detriment.

5. In this manner a mastiff dog was bled into a curr; and the little dog emitted, at least, double the quantity of blood which he could be supposed to possess naturally, when the mastiff died. The curr being untied, ran away and shook himself as if he had been thrown into water.

6. A communication was made between the jugular vein of a calf and a sheep; the former being designed for the emittent, and the latter for the recipient animal. The sheep lost 49 ounces, avoirdupois weight, of blood, before any of the calf's blood was received; and at this time it was judged that the sheep must have been very faint. The calf's blood was then suffered to run into a porringer for 40 seconds, in which time the animal had bled 10 ounces. This was done with a view to ascertain the quantity which should be received by the sheep; but as it could not be supposed that the blood would run so fast into the sheep's vein as into the porringer, the calf was allowed to bleed for five minutes; when it was supposed that the sheep had received as much blood as she had lost. Being then untied, she seemed to have as much strength as before the operation.

7. A sheep, having bled 45 ounces, was supplied with as much or more from a calf; after which she appeared not at all to be hurt by the experiment, but continued lusty and strong.

8. A young land-spaniel was bled to 14 or 16 ounces, which was at the same time supplied by the blood of an old mongrel curr all over-run with the mange; but the spaniel was not in the least hurt by the exchange, though the curr was cured of his mange by the evacuation.

9. The blood of a young dog being transfused into the veins of an old one almost blind with age, the latter began to leap and frisk, though he could hardly stir before. What became of him afterwards is not mentioned.

10. The blood of three calves was transfused into three dogs; after which all the dogs eat as well as before; and one from whom so much blood had been drawn the day before that he could scarcely stir, having been supplied the next morning with the blood of a calf, instantly recovered his strength, and showed a surprising vigour.

11. A bitch, having lost 30 ounces of blood, and being supplied with an equal quantity from some other animal, not only survived that experiment, but also the loss of her spleen, which was afterwards cut out, without tying up the vessels.

12. The blood of one lamb was entirely transfused into another; after which the lamb that had received the blood seemed to be well, and grew like other lambs; but in eight months after the operation it died; whether from the consequences of the transfusion or not, cannot be determined.

13. The blood of a lamb was transfused into the veins of a spaniel 13 years old, who for three years had been so deaf that he was insensible to the loudest noise. He walked very little, and was so feeble, that being unable to lift up his feet, he only trailed his body forward. After the operation he remained for an hour upon the table, then he leaped down, and went to seek his master who was in another room. Two days after he went abroad, and ran up and down the street with other dogs, without trailing his body as he had done formerly. He also began to recover his hearing, and in a month's time had recovered it so far that he always returned at the voice of his master.

14. The blood of four widders was transfused into a horse 26 years old, who by that means was much invigorated, and had his appetite greatly increased.

15. The experiment of transfusing blood into an human vein was performed by Dr Richard Lower and Sir Edmund King, upon one Mr Arthur Coga, on the 23d of November 1667. The manner of doing it is related in the following words. "Having prepared the carotid artery in a young sheep, we made an incision in the vein, observing the method above-mentioned without any alteration but in the shape of one of our pipes, which was found more convenient for our purpose. And having opened the vein in the man's arm with as much ease as in common venæsection, we let thence run out six or seven ounces of blood. Then we planted our silver pipe into the said incision, and inserted quills between the two pipes already advanced in the two subjects, to convey the arterial blood from the sheep into the vein of the man. The blood ran

Lowthorp's Phil. Transf. abridged, vol. III. p. 231.

Transfusion
Transyl-
vania.

freely into the vein for the space of two minutes at least; so that we could feel a pulse in the said vein just beyond the end of the silver pipe. The patient said he did not feel the blood hot, (as had been reported of a man upon whom the like transfusion had been practiced in France); which may very well be imputed to the length of the pipes, through which the blood passed, losing thereby so much of the heat as to come into a temper very agreeable to the venous blood. That the blood did run all the time of those two minutes we conclude from hence. First, Because we felt a pulse during that time. Secondly, Because when, upon the man's saying he thought he had enough, we drew the pipe out of the vein, the sheep's blood ran through it in a full stream; which it would not have done if there had been any stop before, in the space of those two minutes, the blood being so very apt to coagulate in the pipes upon the least stop, especially as the pipes were as long as three quills. From the quantity of blood which run through the pipe into a porringer, we judged that about nine or ten ounces were received into the man's veins. The man, after the operation, as well as in it, found himself very well."

These are very favourable testimonies for this practice. However, according to Heister, it could scarce be ventured upon even in the most desperate cases: "For (says he) almost all the patients who have been this way treated, have degenerated into a stupidity, foolishness, or a raving or melancholy madness; or else have been taken off with sudden death, either in or not long after the operations. These lamentable and fatal consequences have brought the art of injections and transfusion into neglect at present: so that being suspected and condemned by proper judges at Paris, where they most flourished, we are told they were in a little time prohibited by a public edict of that parliament."—Yet, a little after, the same author adds, "But whether or no this method of injecting proper medicines into the blood may succeed, especially in desperate apoplexies, anginas, hydrophobia, &c. and whether it may not be often useful to discharge the morbid blood, and transfuse such as is sound, or warm milk or broth in its stead, ought, in my opinion, to be determined by future and repeated experiment. Burmannus, in his Surgery, (Part III. cap. 31.) tells us, that he has not only performed the operation with success on others, but very happily on himself, being by this means cured not only of a troublesome itch, but also of a stubborn fever."

On the whole, it seems yet to be a matter of doubt whether the infusion of certain liquors, or the transfusion of blood into the veins, ought to be accounted a poisonous operation or a medicinal one; but if ever the transfusion of blood is meddled with, common sense seems to indicate that it is the blood of a human creature which ought to be received by one of the same species, and not that of a beast.

TRANSYLVANIA, a province of Europe, annexed to Hungary, and bounded on the north by Upper Hungary and Poland, on the east by Moldavia and Walachia, on the south by Walachia, and on the west by Upper and Lower Hungary. It is surrounded on all parts by high mountains, which, however, are not barren. The inhabitants have as much corn and wine as they want themselves; and there are

rich mines of gold, silver, lead, copper, quicksilver, and alum. It has undergone various revolutions; but it now belongs to the house of Austria. The inhabitants are of several sorts of religions; as Papists, Lutherans, Calvinists, Socinians, Photinians, Arians, Greeks, and Mahometans. It is about 162 miles in length, and 150 in breadth. The administration of affairs is conducted by 12 persons; namely, three Roman Catholics, three Lutherans, three Calvinists, and three Socinians. The militia is commanded by the governor, whose commission is the more important, as Transylvania is the bulwark of Christendom. It is divided into several small districts, called *palatinates* and *counties*; and is inhabited by three different nations, Saxons, Sicilians, and Hungarians. Hermanstadt is the capital town.

TRAON, or TRAW, a strong and populous town of the republic of Venice, in Dalmatia, with a bishop's see, seated on the gulph of Venice, in a small island, joined to Terra Firma by a long bridge of wood, and to the isle of Bua by another of stone. It is not very large, but strong and populous. E. Long. 17. 10. N. Lat. 43. 50.

TRAPANI, or TRAPANO, a town of Italy in Sicily, seated on the west side of it, in the Val-di-Mazara, with a harbour and a castle. It is seated in a small peninsula, and built in the form of a sickle; is a trading place, and the harbour defended by a fort. It is famous for its salt-works, and its fisheries of tunnies and coral. E. Long. 12. 45. N. Lat. 38. 5.

TRANSIT, in astronomy, signifies the passage of any planet just by or over a fixed star or the sun; and of the moon, in particular, covering or moving over any star. See ASTRONOMY, n° 193.

TRANSITION, the passage of any thing from one place to another.

TRANSITION, in oratory. See ORATORY, n° 38.

TRANSITIVE, in grammar, an epithet applied to such verbs as signify an action which passes from the subject that does it, to or upon another subject which receives it. Under the head of verbs transitive come what we usually call *verbi active* and *passive*; other verbs, whose action does not pass out of themselves, are called *neuters*.

TRANSLATION, the act of transferring or removing a thing from one place to another; as we say, the translation of a bishop's see, a council, a seat of justice, &c.

TRANSLATION is also used for the version of a book or writing, out of one language into another.

TRANSMARINE, something that comes from or belongs to the parts beyond seas.

TRANSMIGRATION, the removal or translation of a whole people into another country, by the power of a conqueror.

TRANSMIGRATION is particularly used for the passage of the soul out of one body into another, being the same with what we otherwise call METEMPSYCHOSIS.

TRANSMUTATION, the act of changing or transforming one nature into another.

TRANSMUTATION of Acids. See CHEMISTRY, n° 170, 192, 219.

TRANSMUTATION of Metals. See CHEMISTRY, n° 351, 374, 423.

Tranon
Transmu-
tation.

Transom
||
Transposition
||
Traverse.

TRANSOM, among builders, denotes the piece that is framed across a double-light window.

TRANSOMS, in a ship, certain beams or timbers extended across the stern-post of a ship, to fortify her after-part, and give it the figure most suitable to the service for which she is calculated.—Transoms are here defined beams or timbers, because they partake equally of the form and purpose of those pieces. Thus the deck-transom is the aftmost or hindmost beam of the lower deck, whereon all the deck-planks are rabbeted: and all the transoms are fixed athwart the stern-post, in the same manner as the floor-timbers are laid upon the keel. As the floor-timbers also, with regard to their general form and arrangement, have a rising, by which the bottom becomes narrower as it ascends towards the extremities; so the arms of the transoms, being gradually closer in proportion to their distance from the wing-transom downwards, give a similar figure to that part of the ship, which accordingly becomes extremely narrow, from the counter towards the keel; and this general figure or curve is called the *flight of the transoms*.—Although these pieces are therefore extremely different in their figures, according to the extent of the angles formed by their branches or horns, each of them has nevertheless a double curve, which is partly vertical and partly horizontal, with regard to its situation in the ship. The former of these is called by the artificers the *round-up*, and the latter the *round-ast*.—As the transoms fill up the whole space comprehended between the head of the stern-post above and the aftmost floor-timbers below, it is necessary to distinguish them by particular names. Thus the highest is called the *wing transom*; the next, the *deck-transom*; and afterwards follow the first, second, and third transoms; together with the intermediate ones.—The vertical direction of the arms or angles of the transoms, with regard to the ship's length, are expressed in the plane of *Elevation*, and their horizontal curves are also delineated on the plane of *Projection*. See *SHIP-BUILDING*.—The highest transoms are connected to the ship's quarter by knees, which are bolted to those pieces and to the after-timbers.

TRANSPARENCY, in physics, a quality in certain bodies, whereby they give passage to the rays of light; in contradistinction to opacity, or that quality of bodies which renders them impervious to the rays of light.

It has been generally supposed by philosophers, that transparent bodies have their pores disposed in straight lines, by which means the rays of light have an opportunity of penetrating them in all directions; but some experiments in electricity have made it apparent, that by the action of this fluid the most opaque bodies, such as sulphur, pitch, and sealing-wax, may be rendered transparent as glass, while yet we cannot suppose the direction of their pores to be any way altered from what it originally was. A curious instance of an increase of transparency we have in rubbing a piece of white paper over one that has been written upon or printed: while the white paper is at rest, the writing or print will perhaps scarce appear through it; but when in motion, will be very easily legible, and continue so till the motion is discontinued.

TRANSPPOSITION, in grammar, a disturbing or dislocating the words of a discourse, or a changing

their natural order of construction, to please the ear by rendering the contexture more smooth, easy, and harmonious.

TRANSPPOSITION, in music. See Music, par. 236. the note.

TRANSUBSTANTIATION, in theology, the conversion or change of the substance of the bread and wine in the eucharist, into the body and blood of Jesus Christ; which the Romish church suppose to be wrought by the consecration of the priest.

TRANSVERSALIS, in anatomy. See there, *Table of the Muscles*.

TRANSVERSE, something that goes across another from corner to corner: thus bends and bars in heraldry are transverse pieces or bearings; the diagonals of a parallelogram or a square are transverse lines.

TRAPEZIUM, in geometry, a plane figure contained by four unequal right lines.

TRAPEZIUS, in anatomy. See there, *Table of the Muscles*.

TRAPP (Dr Joseph), an English divine of excellent parts and learning, was born at Cherington in Gloucestershire, of which place his father was rector in 1579. He was the first person chosen to the professorship of poetry founded at Oxford by Dr Birkhead; and published his lectures under the title of *Praelectiones Poeticae*, in which he laid down excellent rules for every species of poetry in very elegant Latin. He showed afterwards, however, by his translation of Virgil, that a man may be able to direct who cannot execute, and may have the critic's judgment without the poet's fire. In the early part of his life Dr Trapp is said to have been chaplain to the father of the famous lord Bolingbroke; he obtained the living of Christ-church in Newgate Street, and St Leonard's, Foster-lane, London; and his very high-church principles probably obstructed his farther preferment. He published several occasional poems, a tragedy called *Abramule*, translated Milton's *Paradise Lost* into Latin verse, and died in 1747.

TRAVERSE, or **TRANSVERSE**, in general, denotes something that goes athwart another; that is, crosses and cuts it obliquely.

TRAVERSE, in navigation, implies a compound course, or an assemblage of various courses, lying at different angles with the meridian. Thus fig. 6. Plate CCLXXVI. exhibits the traverses formed by a ship, when making an oblique progression against the direction of the wind, as explained in the article **TACKLING**.

The true course and distance resulting from this diversity of courses is discovered by collecting the difference of latitude and departure of each course, and reducing the whole into one departure and one difference of latitude, according to the known rules of trigonometry. This reduction will immediately ascertain the base and perpendicular; or, in other words, will give the difference of latitude and departure to discover the course and distance. See **NAVIGATION**.

TRAVERSE-Board, a thin circular piece of board, marked with all the points of the compass, and having eight holes bored in each, and eight small pegs hanging from the centre of the board. It is used to determine the different courses run by a ship during the

Traspe-
fition
||
Traverse.

See
Electricity,
p. 4.

Treach,
Treason.

the period of the watch, and to ascertain the distance of each course. This implement is particularly useful in light and variable winds, at which time the helmsman marks the course every half hour, by fixing a peg in that point of the compass whereon the ship had advanced. Thus, if the wind is northerly at the beginning of the watch, the ship, being close-hauled on the larboard tack, will steer W. N. W. If, after the first half hour, the wind changes to N. by W. the ship will fall off to W. by N. both of these courses are marked by the helmsman upon the traverse-board, by putting in one peg for every half hour on which she steers the same course; as, one peg into W. N. W. and two pegs into W. by N. if she sails an hour on the latter course; and so on. The lee-way and variation of the compass are afterwards allowed by the pilot, on summing up the whole.

TREACLE. See THERIACA.—Some also give the name *treacle* to melleas.

TREASON (*proditio*), in its very name (which is borrowed from the French) imports a betraying, treachery, or breach of faith. It therefore happens only between allies, faith the Mirror of Justice: for treason is indeed a general appellation, made use of by the law, to denote not only offences against the king and government; but also that accumulation of guilt which arises whenever a superior reposes a confidence in a subject or inferior, between whom and himself there subsists a natural, a civil, or even a spiritual relation; and the inferior so abuses that confidence, so forgets the obligations of duty, subjection, and allegiance, as to destroy the life of any such superior or lord. This is looked upon as proceeding from the same principle of treachery in private life, as would have urged him who harbours it to have conspired in public against his liege lord and sovereign: and therefore for a wife to kill her lord or husband, a servant his lord or master, and an ecclesiastic his lord or ordinary; these, being breaches of the lower allegiance, of private and domestic faith, are denominated *petit* treasons. But when disloyalty so rears its crest, as to attack even majesty itself, it is called by way of eminent distinction *high-treason*, *alta proditio*; being equivalent to the *crimen lese majestatis* of the Romans; as Glanvil denominates it also in our English law.

High-Treason. As this is the highest civil crime, which (considered as a member of the community) any man can possibly commit, it ought therefore to be the most precisely ascertained. For if the crime of high-treason be indeterminate, this alone (says the president Montesquieu) is sufficient to make any government degenerate into arbitrary power. And yet, by the ancient common law, there was a great latitude left in the breast of the judges, to determine what was treason, or not so: whereby the creatures of tyrannical princes had opportunity to create abundance of constructive treasons; that is, to raise, by forced and arbitrary constructions, offences into the crime and punishment of treason, which never were suspected to be such. But to prevent the inconveniences which began to arise in England from this multitude of constructive treasons, the statute 25 Edw. III. c. 2. was made; which defines what offences only for the future should be held to be treason: in like manner as the *lex Julia majestatis* among the Romans, promulgated by Au-

gustus Cæsar, comprehended all the ancient laws that had before been enacted to punish transgressors against the state. This statute must therefore be our guide, in order to examine into the several species of high-treason. And we shall find that it comprehends all kinds of high-treason under seven distinct branches.

1. When a man doth compass or imagine the death of our lord the king, of our lady his queen, or of their eldest son and heir." Under this description it is held that a queen-regnant (such as queen Elizabeth and queen Anne) is within the words of the act, being invested with royal power and entitled to the allegiance of her subject: but the husband of such a queen is not comprised within these words; and therefore no treason can be committed against him.

Let us next fee what is a *compassing* or *imagining* the death of the king, &c. These are synonymous terms: the word *compass* signifying the purpose or design of the mind or will; and not, as in common speech, the carrying such design to effect. And therefore an accidental stroke, which may mortally wound the sovereign, *per infortunium*, without any traitorous intent, is no treason: as was the case of Sir Walter Tyrrel, who, by the command of king William Rufus, shooting at a hart, the arrow glanced against a tree, and killed the king upon the spot. But as this compassing or imagination is an act of the mind, it cannot possibly fall under any judicial cognizance, unless it be demonstrated by some open or overt act. And yet the tyrant Dionysius is recorded to have executed a subject barely for dreaming that he had killed him; which was held for a sufficient proof, that he had thought thereof in his waking hours. But such is not the temper of the English law; and therefore in this, and the three next species of treason, it is necessary that there appear an open or overt act of a more full and explicit nature, to convict the traitor upon. The statute expressly requires, that the accused "be thereof upon sufficient proof attained of some open act by men of his own condition." Thus, to provide weapons or ammunition for the purpose of killing the king, is held to be a palpable overt act of treason in imagining his death. To conspire to imprison the king by force, and move towards it by assembling company, is an overt act of compassing the king's death; for all force, used to the person of the king, in its consequence may tend to his death, and is a strong presumption of something worse intended than the present force, by such as have so far thrown off their bounden duty to their sovereign: it being an old observation, that there is generally but a short interval between the prisons and the graves of princes.

How far mere words spoken by an individual, and not relative to any treasonable act or design then in agitation, shall amount to treason, has been formerly matter of doubt. We have two instances in the reign of Edward IV. of persons executed for treasonable words: the one a citizen of London, who said he would make his son heir of the crown, being the sign of the house in which he lived; the other a gentleman, whose favourite buck the king killed in hunting, whereupon he wished it, horns and all, in the king's belly. These were esteemed hard cases: and the chief justice Markham rather chose to leave his place than assent to the latter judgment. But now it seems clearly to be agreed, that

Treason.

Black.
Comment.

that

that by the common law and the statute of Edw. III. words spoken amount only to a high misdemeanor, and no treason. For they may be spoken in heat, without any intention; or be mistaken, perverted, or misremembered by the hearers; their meaning depends always on their connection with other words and things; they may signify differently even according to the tone of voice with which they are delivered; and sometimes silence itself is more expressive than any discourse. As therefore there can be nothing more equivocal and ambiguous than words, it would indeed be unreasonable to make them amount to high-treason. And accordingly, in 4 Car. I. on a reference to all the judges, concerning some very atrocious words spoken by one Pyne, they certified to the king, "that though the words were as wicked as might be, yet they were no treason: for unless it be by some particular statute, no words will be treason." If the words be set down in writing, it argues more deliberate intention; and it has been held, that writing is an overt act of treason; for *scribere est agere*. But even in this case the bare words are not the treason, but the deliberate act of writing them. And such writing, though unpublished, has in some arbitrary reigns convicted its author of treason: particularly in the cases of one Peacham a clergyman, for treasonable passages in a sermon never preached; and of Algernon Sidney, for some papers found in his closet: which, had they been plainly relative to any previous formed design of dethroning or murdering the king, might doubtless have been properly read in evidence as overt acts of that treason which was specially laid in the indictment; but being merely speculative, without any intention (so far as appeared) of making any public use of them, the convicting the authors of treason upon such an insufficient foundation has been universally disapproved. Peacham was therefore pardoned: and though Sidney indeed was executed, yet it was to the general discontent of the nation; and his attainder was afterwards reversed by parliament. There was then no manner of doubt, but that the publication of such a treasonable writing was a sufficient overt act of treason at the common law; though of late even that has been questioned.

2. The second species of treason is, "if a man do violate the king's companion, or the king's eldest daughter unmarried, or the wife of the king's eldest son and heir." By the king's companion is meant his wife; and by violation is understood carnal knowledge, as well without force as with it: and this is high-treason in both parties, if both be consenting; as some of the wives of Henry VIII. by fatal experience evinced. The plain intention of this law is to guard the blood-royal from any suspicion of bastardy, whereby the succession to the crown might be rendered dubious; and therefore, when this reason ceases, the law ceases with it; for to violate a queen or princess dowager is held to be no treason: in like manner as, by the feudal law, it was a felony, and attended with a forfeiture of the fief, if the vassal violated the wife or daughter of his lord; but not so if he only violated his widow.

3. The third species of treason is, "if a man do levy war against our lord the king in his realm." And this may be done by taking arms, not only to dethrone the king, but under pretence to reform religion, or the laws, or to remove evil counsellors, or other grievances

whether real or pretended. For the law does not, neither can it permit any private man, or set of men, to interfere forcibly in matters of such high importance; especially as it has established a sufficient power for these purposes in the high court of parliament: neither does the constitution justify any private or particular resistance for private or particular grievances; though, in cases of national oppression, the nation has very justifiably risen as one man, to vindicate the original contract subsisting between the king and his people.

4. "If a man be adherent to the king's enemies in his realm, giving to them aid and comfort in the realm, or elsewhere," he is also declared guilty of high-treason. This must likewise be proved by some overt act; as by giving them intelligence, by sending them provisions, by selling them arms, by treacherously surrendering a fortress, or the like.

5. "If a man counterfeit the king's great or privy seal," this is also high-treason. But if a man takes wax bearing the impression of the great seal off from one patent and fixes it to another, this is held to be only an abuse of the seal, and not a counterfeiting of it: as was the case of a certain chaplain, who in such a manner framed a dispensation for non-residence. But the knavish artifice of a lawyer much exceeded this: the divine. One of the clerks in chancery glued together two pieces of parchment; on the uppermost of which he wrote a patent, to which he regularly obtained the great seal, the label going through both the skins. He then dissolved the cement, and taking off the written patent, on the blank skin wrote a fresh patent of a different import from the former, and published it as true. This was held no counterfeiting of the great seal, but only a great misprison; and Sir Edward Coke mentions it with some indignation, that the party was living at that day.

6. The sixth species of treason under this statute is, "if a man counterfeit the king's money; and if a man bring false money into the realm counterfeit to the money of England, knowing the money to be false, to merchandise and make payment withal." As to the first branch, counterfeiting the king's money; this is treason, whether the false money be uttered in payment or not. Also if the king's own minters alter the standard or alloy established by law, it is treason. But gold and silver money only are held to be within this statute. With regard likewise to the second branch, importing foreign counterfeit money in order to utter it here; it is held that uttering it, without importing it, is not within the statute.

7. The last species of treason ascertained by this statute is, "if a man slay the chancellor, treasurer, or the king's justices of the one bench or the other, justices in eyre, or justices of assize, and all other justices assigned to hear and determine, being in their places doing their offices." These high magistrates, as they represent the king's majesty during the execution of their offices, are therefore for the time equally regarded by the law. But this statute extends only to the actual killing of them; and not to wounding, or a bare attempt to kill them. It extends also only to the officers therein specified; and therefore the barons of the exchequer, as such, are not within the protection of this act: but the lord keeper or commissioners of the great seal now seem to be within it, by virtue

Temporary statutes of late times enacted, have made some other offences treasonable, as relating to Papists and the Protestant succession.

The punishment of high-treason in general is very solemn and terrible. 1. That the offender be drawn to the gallows, and not be carried or walk; though usually (by connivance, at length ripened by humanity into law) a sledge or hurdle is allowed, to preserve the offender from the extreme torment of being dragged on the ground or pavement. 2. That he be hanged by the neck, and then cut down alive. 3. That his entrails be taken out, and burned, while he is yet alive. 4. That his head be cut off. 5. That his body be divided into four parts. 6. That his head and quarters be at the king's disposal.

The king may, and often doth, discharge all the punishment except beheading, especially where any of noble blood are attained. For beheading being part of the judgment, that may be executed, though all the rest be omitted by the king's command. But where beheading is no part of the judgment, as in murder or other felonies, it hath been said that the king cannot change the judgment, although at the request of the party, from one species of death to another.

In the case of coining, which is a treason of a different complexion from the rest, the punishment is milder for male offenders; being only to be drawn and hanged by the neck till dead. But in treasons of every kind the punishment of women is the same, and different from that of men. For as the natural modesty of the sex forbids the exposing and publicly mangling their bodies, their sentence (which is to the full as terrible to sense as the other) is to be drawn to the gallows, and there to be burned alive.

For the consequences of this judgment, see ATTAINDER, FORFEITURE, and CORRUPTION of Blood.

Petit TREASON, according to the statute 25 Edward III. c. 2. may happen three ways: by a servant killing his master, a wife her husband, or an ecclesiastical person (either secular or regular) his superior, to whom he owes faith and obedience. See TREASON. A servant who kills his master whom he has left, upon a grudge conceived against him during his service, is guilty of *petit treason*: for the traitorous intention was hatched while the relation subsisted between them, and this is only an execution of that intention. So if a wife be divorced *a mensa et thoro*, still the vinculum matrimonii subsists; and if she kills such divorced husband, she is a traitress. And a clergyman is understood to owe canonical obedience to the bishop who ordained him, to him in whose diocese he is beneficed, and also to the metropolitan of such suffragan or diocesan bishop; and therefore to kill any of these is *petit treason*. As to the rest, whatever has been said with respect to wilful MURDER, is also applicable to the crime of *petit treason*, which is no other than murder in its most odious degree; except that the trial shall be as in cases of high-treason, before the improvements therein made by the statutes of William III. But a person indicted of *petit treason* may be acquitted thereof, and found guilty of manslaughter or murder: and in such case it should seem that two witnesses are not necessary, as in case of

petit treason they are. Which crime is also distinguish- ed from murder in its punishment.

The punishment of *petit treason* in a man, is to be drawn and hanged, and in a woman to be drawn and burned: the idea of which latter punishment seems to have been handed down to us from the laws of the ancient Druids, which condemned a woman to be burned for murdering her husband; and it is now the usual punishment for all sorts of treasons committed by those of the female sex. Persons guilty of *petit treason* were first debarred the benefit of clergy by statute 12 Henry VII. c. 7. which has since been extended to their aiders, abettors, and counsellors, by statutes 23 Henry VIII. c. 1. and 4 & 5 P. and M. c. 4.

TREASURE, in general, denotes a store or stock of money in reserve.

TREASURE-Trove, in law, derived from the French word *trouver*, "to find," called in Latin *thesaurus inventus*, is where any money or coin, gold, silver, plate, or bullion, is found hidden in the earth, or other private place, the owner thereof being unknown; in which case the treasure belongs to the king: but if he that hid it be known, or afterwards found out, the owner and not the king is entitled to it. Also if it be found in the sea, or upon the earth, it doth not belong to the king but the finder, if no owner appears. So that it seems it is the hiding, not the abandoning of it, that gives the king a property: Bracton defining it, in the words of the civilians, to be *vetus depositio pecunie*. This difference clearly arises from the different intentions which the law implies in the owner. A man that hides his treasure in a secret place, evidently does not mean to relinquish his property, but reserves a right of claiming it again when he sees occasion; and if he dies and the secret also dies with him, the law gives it the king in part of his royal revenue. But a man that scatters his treasure into the sea, or upon the public surface of the earth, is construed to have absolutely abandoned his property, and returned it into the common stock, without any intention of reclaiming it: and therefore it belongs, as in a state of nature, to the first occupant or finder; unless the owner appear and assert his right, which then proves that the loss was by accident, and not with an intent to renounce his property.

Formerly all treasure-trove belonged to the finder; as was also the rule of the civil law. Afterwards it was judged expedient for the purposes of the state, and particularly for the coinage, to allow part of what was found to the king, which part was assigned to be all hidden treasure; such as is casually lost and unclaimed, and also such as is designedly abandoned, still remaining the right of the fortunate finder. And that the prince shall be entitled to this hidden treasure is now grown to be, according to Grotius, *jus commune, et quasi gentium*: for it is not only observed, he adds, in England, but in Germany, France, Spain, and Denmark. The finding of deposited treasure was much more frequent, and the treasures themselves more considerable, in the infancy of our constitution than at present. When the Romans, and other inhabitants of the respective countries which composed their empire, were driven out by the northern nations, they concealed their money under ground, with a view of resorting to

Treasurer
||
Trec.Trefoil
||
Trenchard.

to it again when the heat of the irruption should be over, and the invaders driven back to their desarts. But as this never happened, the treasures were never claimed; and on the death of the owners the secret also died along with them. The conquering generals being aware of the value of these hidden mines, made it highly penal to secrete them from the public service. In England therefore, as among the feudists, the punishment of such as concealed from the king the finding of hidden treasure was formerly no less than death; but now it is only fine and imprisonment.

TREASURER, an officer to whom the treasure of a prince or corporation is committed to be kept and duly disposed of.

The lord high treasurer of Great Britain, or first commissioner of the treasury, when in commission, has under his charge and government all the king's revenue which is kept in the exchequer. He holds his place during the king's pleasure; being instituted by the delivery of a white staff to him. He has the check of all the officers employed in collecting the customs and royal revenues: and in his gift and disposition are all the offices of the customs in the several ports of the kingdom; cheats in every county are nominated by him; he also makes leases of the lands belonging to the crown.

TREASURY, the place wherein the revenues of a prince are received, preserved, and disbursed.

Lords of the TREASURY. In lieu of one single director and administrator of his Majesty's revenues under the title of *lord high treasurer*, it is at present thought proper to put that office in commission, *i. e.* to appoint several persons to discharge it with equal authority, under the title of *lords commissioners of the treasury*.

TREATISE, a set discourse in writing on any subject.

TREATY, a covenant between two or more nations; or the several articles or conditions stipulated and agreed upon between sovereign powers.

TREBLE, in music, the highest or most acute of the four parts in symphony, or that which is heard the clearest and shrillest in a concert.

TREBUCHET, **TREBUCKET**, *Tribuch*, (*Terbuchetum*), a tumbril or cucking stool. Also a great engine to cast stones to batter walls.

TREE, the first and largest of the vegetable kind, consisting of a single trunk, out of which proceed branches and leaves.—Trees are by Linnaeus classed in the seventh family of the vegetable kingdom, and are distinguished from shrubs in that their stems come up with buds on them: but this distinction holds not universally, there being rarely any buds on the large trees in India.

It has been directed by Dr Hales and Mr Evelyn to wash and rub the stems of trees in order to promote their growth; and in the 67th vol. of the Philos. Transact. we have an account of the success of this method. Mr Marsham, in his letter to the lord bishop of Bath and Wells, informs us, that a tree so washed increased fully double the quantity in girth that an unwashed tree did. It was between 13 and 14 feet in height. He washed it from the ground to the beginning of the head, first using water and a stiff shoe-brush until the stem was well cleared from moss

and dirt, and then using only a coarse flannel. The washing was begun as soon as the buds began to swell, and continued three four or five times a-week during all the dry time of the spring and forepart of the summer; but seldom after rains became frequent.—The same gentleman informs us, that a short and spreading tree, having ample room, will increase twice or three times, and perhaps four times, as much as a tall small-headed tree of the same age that stands near other trees.

TREFOIL, in botany. See **TRIFOLIUM**.

TREMELLA, in botany, a genus of aquatic plants of a middle nature between the alga and conserva, being of a pellucid and membranaceous, and frequently gelatinous, nature. There are nine species; the most remarkable of which is the *plicata undulata*, or gelly rain tremella, found in pastures, and by the sides of gravel-walks in gardens after rains; not uncommon in spring, summer, and autumn. It is a membranaceous, pellucid, and gelatinous substance, without any visible root; of a yellowish dull green colour; assuming various forms, either round, angular, plaited or folded together irregularly, like the intestines or a pocket-handkerchief, an inch or two or more in diameter: soft to the touch when moist; but thin, membranaceous, and brittle, when dry; and of a black fuscous colour.—The ancient alchemists called this vegetable the *flowers of heaven*, and imagined that from it they would procure the universal menstruum: but all their researches ended in discovering that by distillation it yielded some phlegm, volatile salt, and empyreumatic oil. It has been extolled in wounds, ulcers, &c. but no regard is ever paid to it by judicious practitioners.

TREMELLIUS (Emmanuel), a Jew by birth, was born at Ferrara in the year 1510. He was so carefully educated as to become a great master of the Hebrew tongue; but was converted to Christianity by the celebrated Peter Martyr. After travelling to Germany and England, he was made professor of the Hebrew tongue, first at Heidelberg, and then at Sedan, where he died in 1580. He translated the Hebrew Bible and Syriac Testament into Latin; in the former he was assisted by Junius, who afterward corrected the second edition in 1587. This work was received by the Protestant churches with great approbation.

TREMOR, an involuntary shaking, chiefly of the hands and head, sometimes of the feet, and sometimes of the tongue and heart.—Tremors arising from a too free use of spirituous liquors require the same treatment as palfies.

TRENCHES, in fortification, are ditches cut by the besiegers, that they may approach the more securely to the place attacked; whence they are also called *lines of approach*.

TRENCHARD (John), an eminent English writer, was descended from an ancient family, and born in the year 1669. He had a liberal education; and was bred to the law, in which he made great progress: but politics, and the place of commissioner of the forfeited estates of Ireland, which he enjoyed in the reign of king William, took him from the bar. He began early to distinguish himself by his writings: for, in 1697, he published, *An argument showing that a standing army is inconsistent with a free govern-*

Trent
||
Tret.

ment, and absolutely destructive to the constitution of the English monarchy; and the year following he published a short history of the standing armies in England: which gave occasion to several answers. In 1720, Mr Trenchard, in conjunction with Mr Thomas Gordon, began to publish in the London, and afterwards in the British Journal, a series of letters, under the name of *Cato*, upon various public and important subjects, which were continued for near three years with great reputation, and afterwards collected and published by Mr Gordon in 4 vols 12mo, under the title of *Cato's Letters*. Mr Trenchard was member of parliament for Taunton in Somersetshire; and died in 1723. Mr Gordon gives him the character of being "one of the worthiest, one of the ablest, one of the most useful men, that ever any country was blessed withal."

TRENT (bifhopric of), a province of Germany, in the circle of Auflria, near the frontiers of Italy, is bounded on the north by Tirol; on the east, by the Feltrino and Bellunese; on the south, by Vicentino, the Veronese, Brefciano, and the lake de Garda; and on the west, by the Brefciano and the lake de Garda. The soil is said to be pretty fruitful, and to abound in wine and oil.

TRENT, a city of Germany, and capital of the bifhopric of that name; is a very ancient place, and stands in a fertile and pleasant plain, in the midst of the high mountains of the Alps. The river Adige washes its walls, and, creeping for some time among the hills, runs swiftly into Italy. Trent has three considerable churches, the principal of which is the cathedral: this is a very regular piece of architecture. The church of St Maria Major, is all of red and white marble; and is remarkable for being the place where the famous council of Trent was held, whose decisions are now the standing rule of the Romish church. E. Long. 11. 5. N. Lat. 46. 10.

TRENT, one of the largest rivers in Egglund, which rises in the Moorland of Staffordshire, and runs south-west by Newcastle-under-Line; and afterwards dividing the county in two parts, runs to Burton, then to Nottingham and Newark; and so continuing its course due north to Gainfborough on the confines of Lincolnshire, it joins several rivers, and falls into the Humber.

TREPANNING, in surgery. See there, n^o 511. et seq.

TRES TAERNÆ, (anc. geog.) a place in Latium, lying on the Via Appia, on the left or south side of the river Astura, to the north of the Paludes Pompinæ. Its ruins now seen near Cisterna, a village in the Campagna di Roma, twenty-one miles from Rome, whence the Christians went out to meet St Paul.

TRESPASS, in law, signifies any transgression of the law, under treason, felony, or misprison of either: but it is commonly used for any wrong or damage that is done by one private person to another, or to the king in his forest.

TRESSLE-TREES, in ship-building, two strong bars of timber fixed horizontally on the opposite sides of the lower mast-head, to support the frame of the top and the weight of the top-mast.

TRESSURE, in heraldry, a diminutive of an orle, usually held to be half the breadth thereof.

TRET, in commerce, an allowance made for the

waste or the dirt that may be mixed with any commodity; which is always four pounds in every 104 pounds weight.

TREVERI, or TREVIRI, (anc. geog.) an ancient and a powerful people both in horse and foot, according to Cæsar; extending far and wide between the Meuse and the Rhine. In the lower age their capital, called *Augusta Trevirorum*, assumed, after the manner of those times, the name of the people, *Treviri*. Now *Triers* or *Treves*, capital of the electorate of that name, situate on the Moselle. E. Long. 6. 10. Lat. 49. 55.

TREVES, an archbifhopric of Germany; lies between Cologne, Berg, and Juliers on the north, Lorrain and the Palatinate on the south, Luxemburg on the west, and the Wetterau on the east. Its extent from south to north is about 80 miles; but its breadth is very unequal. On the banks of the Rhine and Moselle, the country is populous, and fruitful in corn and wine; but elsewhere mountainous and woody, yet abounding in game, and in metals and minerals of various kinds. It is watered not only by the Rhine and Moselle, but also by the Saar and Kyll, and contains 28 towns. The states consist of the prelates or abbots, with the representatives of the clergy, and of certain towns. The inhabitants are all Papists, except in such places as the elector possesses in common with other princes, where there are some Protestants. Under the archbifhop are five archdeacons, and, subordinate to these, 20 provincial deans. The church of Treves, is commonly accounted the most ancient of Germany. The chapter which elects the archbifhop from among themselves, and makes him swear to a capitulation, consists of 16 capitulary canons, who are all of noble extraction, besides 24 others, who are domiciled. At every new election, the pope receives large sums for confirmation, the pallium, and for annats. The archiepiscopal title is, By the grace of God, archbifhop of Treves, of the holy Roman empire throughout Gaul and the kingdom of Arles, arch-chancellor and elector, and also administrator of Prum. He is the second elector in rank, and at the election of an emperor has the first voice. His matricular assessment is 26 horse and two-thirds, and 122 foot two-thirds, or 806 florins 40 kruitzers. In the diets of the circle he has the second place, and nominates one assessor of the chamber judicatory, towards the maintenance of which he contributes, each term, 811 rix-dollars 58 kruitzers. The tolls on the Moselle and Rhine, his demefnes, and his office of noble guardian of the minors, with the taxes he lays on his subjects, are supposed to bring him in about 70,000 *per annum*. For the government of this electorate and the administration of justice, besides the regency and revision-court, there are the two anlic judicatories, to which appeals lie from the inferior courts. There are also two spiritual high-courts. The hereditary officers are the marshal, the chamberlain, the sewer, and cupbearer. Among other prerogatives, this elector has power to banish excommunicated persons out of the empire if they do not reconcile themselves to the church within a-year, and to take possession of the estates of minors till they are of age. He has also a right to reunite all the fiefs of his diocese, upon failure of heirs, to the domains of his church. His

Trial.

subjects may appeal to the chamber of the empire in all causes above a thousand florins. The regular troops he maintains, besides a militia, amount to between 1100 and 1200, besides a life-guard of 40 men.

TREVES or Trier, in Latin *Trevere, Trevers, Treviris*, or *Augusta Trevirorum*, the capital of a German archbishopric of the same name; it stands 60 miles west of Mentz, 52 south of Cologne, and 82 north of Strasburg. This city vies with most in Europe for antiquity, having been a large and noted town before Augustus settled a colony in it. It was free and imperial till the year 1560, when it was surprised and subjected by its archbishop James III. It stands on the Moselle, over which it has a fair stone bridge. The cathedral is a large building; and near it stands the elector's palace, which not long ago was rebuilt. Here are three collegiate and five parish-churches, three colleges of Jesuits, thirteen monasteries and nunneries, an university founded in 1472, a house of the Teutonic order, and another of that of Malta, with some remains of the ancient Roman theatre. Roman coins and medals are often found in the ruins of the old city. In the cathedral they pretend to have our Saviour's coat and St Peter's staff, to which they ascribe miracles. The private houses here are mean; and the city is neither well fortified, nor inhabited. E. Long. 6. 10. N. Lat. 49. 58.

TRIAL, in law, the examination of a cause according to the laws of the land before a proper judge; or it is the manner and order observed in the hearing and determining of causes. See SUIT, WRIT, PROCESS, PLEADINGS, ISSUE (in APPENDIX), PROSECUTION, ARRAIGNMENT, and PLEA.

Trials are either civil or criminal.

I. *Civil TRIALS*. The species of trials in civil cases are seven: By record; by inspection, or examination; by certificate; by witnesses; by wager of battle; by wager of law; and by jury. The first six are only had in certain special or exceptional cases, where the trial by jury would not be so proper or effectual: See them explained under their respective titles. The nature of the last, that principal criterion of truth in the law of England, shall be explained in this article.

The method of trial by jury, called also the trial *per pais*, or *by the country*, hath been used time out of mind in this nation, and seems to have been coeval with the first civil government thereof. Its use, though for a time greatly impaired and shaken by the introduction of the Norman trial by battle, was always so highly esteemed and valued by the people, that no conquest, no change of government, could ever prevail to abolish it: and in *magna charta* it is more than once insisted on as the principal bulwark of our liberties.

Trials by jury in civil causes are of two kinds; *extraordinary* and *ordinary*.

1. The first species of *extraordinary* trial by jury is that of the grand assize, which was instituted by king Henry II. in parliament, by way of alternative offered to the choice of the tenant or defendant in a writ of right, instead of the barbarous and unchristian custom of duelling. For this purpose a *writ de magna assisa eligenda* is directed to the sheriff, to return four knights, who are to elect and choose 12 others to be joined with them; and these all together form the grand assize,

or great jury, which is to try the matter of right, and mult now consist of 16 jurors. Another species of extraordinary juries, is the jury to try an attain; which is a process commenced against a former jury for bringing a false verdict. See the article ATTAIN.

2. With regard to the *ordinary* trial by jury in civil cases, the most clear and perspicuous way of treating it will be by following the order and course of the proceedings themselves.

When therefore an issue is joined by these words, "And this the said A prays may be inquired of by the country;" or, "And of this he puts himself upon the country, and the said B does the like;" the court awards a writ of *venire facias* upon the roll or record, commanding the sheriff "that he cause to come here, on such a day, twelve free and lawful men, *liberes et legales homines*, of the body of his county, by whom the truth of the matter may be better known, and who are neither of kin to the aforesaid A nor the aforesaid B, to recognize the truth of the issue between the said parties." And such writ is accordingly issued to the sheriff. It is made returnable on the last return of the same term wherein issue is joined, *viz.* hilyary or trinity terms; which, from the making up the issues therein, are usually called *issuable terms*. And he returns the names of the jurors in a panel (a little pane or oblong piece of parchment) annexed to the writ. This jury is not summoned, and therefore not appearing at the day mult unavoidably make default. For which reason a compulsive process is now awarded against the jurors, called in the common pleas a writ of *habeas corpus juratorum*, and in the king's bench *distingas*, commanding the sheriff to have their bodies, or to detain them by their lands and goods, that they may appear upon the day appointed. The entry therefore on the roll of record is, "That the jury is respited, thro' defect of the jurors, till the first day of the next term, to appear at Westminter; unless before that time, *viz.* on Wednesday the fourth of March, the justices of our lord the king appointed to take assizes in that county, shall have come to Oxford, that is, to the place assigned for holding the assize. Therefore the sheriff is commanded to have their bodies at Westminter on the said first day of next term, or before the said justices of assize, if before that time they come to Oxford, *viz.* on the fourth of March aforesaid." And as the judges are sure to come and open the circuit-commissions on the day mentioned in the writ, the sheriff returns and summons this jury to appear at the assizes; and there the trial is had before the justices of assize and *nisi prius*: among whom (as hath been said *), are usually two of the judges of the courts at Westminter, the whole kingdom being divided into six circuits for this purpose. And thus we may observe, that the trial of common issues at *nisi prius*, was in its original only a collateral incident to the original business of the justices of assize; though now, by the various revolutions of practice, it is become their principal civil employment; hardly any thing remaining in use of the real assizes but the name.

If the sheriff be not an indifferent person, as if he be a party in the suit, or be related by either blood or affinity to either of the parties, he is not then trusted to return the jury; but the *venire* shall be directed to the coroners, who in this, as in many other instances,

See the
article
ASSIZE.

Trial.

are the substitutes of the sheriff to execute process when he is deemed an improper person. If any exception lies to the coroners, the *venire* shall be directed to two clerks of the court, or two persons of the county named by the court, and sworn. And these two, who are called *clerks*, or electors, shall indifferently name the jury, and their return is final; no challenge being allowed to their array.

When the general day of trial is fixed, the plaintiff or his attorney must bring down the record to the assizes, and enter it with the proper officer in order to its being called on in court.

These steps being taken, and the cause called on in court, the record is then handed to the judge, to peruse and observe the pleadings, and what issues the parties are to maintain and prove, while the jury is called and sworn. To this end the sheriff returns his compulsive process, the writ of *habeas corpora*, or *disfringas*, with the panel of jurors annexed, to the judge's officer in court.

As the jurors appear when called, they shall be sworn, unless challenged by either party. See the article CHALLENGE.

If by means of challenges, or other cause, a sufficient number of unexceptionable jurors doth not appear at the trial, either party may pray a tales. See the article TALE.

When a sufficient number of persons impanelled, or tales-men appear, they are then separately sworn, well and truly to try the issue between the parties, and a true verdict to give according to the evidence; and hence they are denominated "the jury," *jurata*, and "jurors," *sc. juratores*.

The jury are now ready to hear the merits; and to fix their attention the closer to the facts which they are impanelled and sworn to try, the pleadings are opened to them by counsel on that side which holds the affirmative of the question in issue. For the issue is said to lie, and proof is always first required, upon that side which affirms the matter in question: in which our law agrees with the civil, *ei incumbit probatio qui dicit, non qui negat; cum per rerum naturam factum negantis probatio nulla sit*. The opening counsel briefly informs them what has been transacted in the court above; the parties, the nature of the action, the declaration, the plea, replication, and other proceedings; and lastly, upon what point the issue is joined, which is there sent down to be determined. Instead of which, formerly the whole record and process of the pleadings were read to them in English by the court, and the matter of issue clearly explained to their capacities. The nature of the case, and the evidence intended to be produced, are next laid before them by counsel also on the same side; and when their evidence is gone through, the advocate on the other side opens the adverse case, and supports it by evidence; and then the party which began is heard by way of reply.

When the evidence is gone through on both sides, the judge, in the presence of the parties, the counsel, and all others, sums up the whole to the jury; omitting all superfluous circumstances, observing wherein the main question and principal issue lies, stating what evidence has been given to support it, with such remarks as he thinks necessary for their direction, and

giving them his opinion in matters of law arising upon that evidence.

The jury, after the proofs are summed up, unless the case be very clear, withdraw from the bar to consider of their verdict; and in order to avoid intemperance and causeless delay, are to be kept without meat, drink, fire, or candle, unless by permission of the judge, till they are all unanimously agreed. A method of accelerating unanimity not wholly unknown in other constitutions of Europe, and in matters of greater concern. For by the golden bull of the empire, if, after the congress is opened, the electors delay the election of a king of the Romans for 30 days, they shall be fed only with bread and water till the same is accomplished. But if our juries eat or drink at all, or have any eatables about them, without consent of the court, and before verdict, it is fineable; and if they do so at his charge for whom they afterwards find, it will set aside the verdict. Also if they speak with either of the parties or their agents after they are gone from the bar, or if they receive any fresh evidence in private, or if to prevent disputes they cast lots for whom they shall find, any of these circumstances will entirely vitiate the verdict. And it has been held, that if the jurors do not agree in their verdict before the judges are about to leave the town, though they are not to be threatened or imprisoned, the judges are not bound to wait for them, but may carry them round the circuit from town to town in a cart. This necessity of a total unanimity seems to be peculiar to our own constitution; or at least, in the *membra* or jury of the ancient Goths, there was required (even in criminal cases) only the consent of the major part; and in case of an equality, the defendant was held to be acquitted.

When they are all unanimously agreed, the jury return back to the bar; and before they deliver their verdict, the plaintiff is bound to appear in court, by himself, attorney, or counsel, in order to answer the amendment to which by the old law he is liable, in case he fails in his suit, as a punishment for his false claim. To be amerced, or a *mercie*, is to be at the king's mercy with regard to the fine to be imposed; *in misericordia domini regis pro falso clamore suo*. The amendment is disused, but the form still continues; and if the plaintiff does not appear non verdict can be given; but the plaintiff is said to be nonsuited, *non sequitur clamorem suum*. Therefore it is usual for a plaintiff, when he or his counsel perceives that he has not given evidence sufficient to maintain his issue, to be voluntarily nonsuited, or withdraw himself: whereupon the crier is ordered to call the plaintiff; and if neither he, nor any body for him appears, he is nonsuited, the jurors are discharged, the action is at an end, and the defendant shall recover his costs. The reason of this practice is, that a nonsuit is more eligible for the plaintiff than a verdict against him: for after a nonsuit, which is only a default, he may commence the same suit again for the same cause of action; but after a verdict had, and judgment consequent thereupon, he is for ever barred from attacking the defendant upon the same ground of complaint. But in case the plaintiff appears, the jury by their foreman deliver in their verdict. See the article VERDICT.

When the jury have delivered in their verdict, and

Trial.

Trial.

it is recorded in court, they are then discharged; and so ends the trial by jury: a trial which ever has been, and it is hoped ever will be, looked upon as the glory of the English law. It is certainly the most transcendent privilege which any subject can enjoy or wish for, that he cannot be affected either in his property, his liberty, or his person, but by the unanimous consent of 12 of his neighbours and equals.

The impartial administration of justice, which secures both our persons and our properties, is the great end of civil society. But if that be entirely intrusted to the magistracy, a select body of men, and those generally selected by the prince or such as enjoy the highest offices in the state, their decisions, in spite of their own natural integrity, will have frequently an involuntary bias towards those of their own rank and dignity: it is not to be expected from human nature, that the few should be always attentive to the interests and good of the many. On the other hand, if the power of judicature were placed at random in the hands of the multitude, their decisions would be wild and capricious, and a new rule of action would be every day established in our courts. It is wisely therefore ordered, that the principles and axioms of law, which are general propositions flowing from abstracted reason, and not accommodated to times or to men, should be deposited in the breasts of the judges, to be occasionally applied to such facts as come properly ascertained before them. For here partiality can have little scope; the law is well known, and is the same for all ranks and degrees: it follows as a regular conclusion from the premises of fact pre-established. But in settling and adjusting a question of fact, when intrusted to any single magistrate, partiality and injustice have an ample field to range in; either by boldly asserting that to be proved which is not so, or more artfully by suppressing some circumstances, stretching and warping others, and distinguishing away the remainder. Here therefore a competent number of sensible and upright jurymen, chosen by lot from among those of the middle rank, will be found the best investigators of truth, and the surest guardians of public justice. For the most powerful individual in the state will be cautious of committing any flagrant invasion of another's right, when he knows that the fact of his oppression must be examined and decided by 12 indifferent men not appointed till the hour of trial; and that when once the fact is ascertained, the law must of course redress it. This therefore preserves in the hands of the people that share which they ought to have in the administration of public justice, and prevents the encroachments of the more powerful and wealthy citizens.

II. *Criminal Trials.* The several methods of trial and conviction of offenders, established by the laws of England, were formerly more numerous than at present, through the superition of our Saxon ancestors; who, like other northern nations, were extremely addicted to divination: a character which Tacitus observes of the ancient Germans. They therefore invented a considerable number of methods of purgation or trial, to preserve innocence from the danger of false witnesses, and in consequence of a notion that God would always interpolate miraculously to vindicate the guiltless: as, 1. By ordeal; 2. By corsued; 3. By battel. See these articles.

Trial.

A fourth method is that by the *peers of Great Britain, in the Court of PARLIAMENT*; or the *Court of the Lord High Steward*, when a peer is capitally indicted; for in case of an appeal, a peer shall be tried by jury. This differs little from the trial *per patriam*, or by jury; except that the peers need not all agree in their verdict; and except also, that no special verdict can be given in the trial of a peer: because the lords of parliament, or the lord high steward (if the trial be had in his court) are judges sufficiently competent of the law that may arise from the fact: but the greater number, consisting of 12 at the least, will conclude, and bind the minority.

The trial by jury, or the country, *per patriam*, is also that trial by the peers of every Briton, which, as the great bulwark of his liberties, is secured to him by the great charter: *nullus liber homo capitatur, vel imprisonetur, aut exulet, aut aliquo alio modo destruatur, nisi per legale iudicium parium suorum, vel per legem terre.*

When therefore a prisoner on his *ARRAIGNMENT* has pleaded not guilty, and for his trial hath put himself upon the country, which country the jury are, the sheriff of the county must return a panel of jurors, *liberos et legales homines, de vicineto*; that is, freeholders without just exception, and of the *visne* or neighbourhood; which is interpreted to be of the county where the fact is committed. If the proceedings are before the court of king's bench, there is time allowed between the arraignment and the trial, for a jury to be impanelled by writ of *venire facias* to the sheriff, as in civil causes: and the trial in case of a misdemeanor is had at *nisi prius*, unless it be of such consequence as to merit a trial at bar; which is always invariably had when the prisoner is tried for any capital offence. But, before commissioners of oyer terminer and goal-delivery, the sheriff, by virtue of a general precept directed to him beforehand, returns to the court a panel of 48 jurors, to try all felons that may be called upon their trial at that session; and therefore it is there usual to try all felons immediately or soon after their arraignment.

But it is not customary, nor agreeable to the general course of proceedings, unless by consent of parties, to try persons indicted of smaller misdemeanors at the same court in which they have pleaded not guilty, or traversed the indictment. But they usually give security to the court to appear at the next assizes or session, and then and there to try the traverse, giving notice to the prosecutor of the same.

In cases of high-treason, whereby corruption of blood may ensue (except treason in counterfeiting the king's coin or seals) or misprison of such treason, it is enacted by statute 7 W. III. c. 3. first, that no person shall be tried for any such treason, except an attempt to assassinate the king, unless the indictment be found within three years after the offence committed: next, that the prisoner shall have a copy of the indictment, (which includes the caption) but not the names of the witnesses, five days at least before the trial, that is, upon the true construction of the act, before his arraignment; for then is his time to take any exceptions thereto, by way of plea or demurrer: thirdly, that he shall also have a copy of the panel of jurors two days before his trial: and, lastly, that he shall have the same compulsive process to bring in his witnesses for him

him

him, as was usual to compel their appearance against him. And by statute 7 Ann. c. 21. (which did not take place till after the decease of the late pretender) all persons indicted for high-treason, or misprision thereof, shall have not only a copy of the indictment, but a list of all the witnesses to be produced, and of the jurors impanelled, with their professions and places of abode, delivered to him ten days before the trial, and in the presence of two witnesses, the better to prepare him to make his challenges and defence. And no person indicted for felony is, or (as the law stands) ever can be, entitled to such copies before the time of his trial.

When the trial is called on, the jurors are to be sworn as they appear, to the number of 12, unless they are challenged by the party. See the article CHALLENGE.

If by reason of challenges or the default of the jurors, a sufficient number cannot be had of the original panel, a tales may be awarded as in civil causes, till the number of 12 is sworn, "well and truly to try, and true deliverance make, between our sovereign lord the king and the prisoner whom they have in charge; and a true verdict to give, according to their evidence." See TABLES.

When the jury is sworn, if it be a cause of any consequence, the INDICTMENT is usually opened, and the evidence marshalled, examined, and enforced by the counsel for the crown, or prosecution. But it is a settled rule at common law, that no counsel shall be allowed a prisoner upon his trial upon the general issue, in any capital crime, unless some point of law shall arise proper to be debated. A rule, which (however it may be palliated under cover of that noble declaration of the law, when rightly understood, that the judge shall be counsel for the prisoner; that is, shall see that the proceedings against him are legal and strictly regular) seems to be not at all of a piece with the rest of the humane treatment of prisoners by the English law. For upon what face of reason can that assistance be denied to save the life a man, which yet is allowed him in prosecutions for every petty trespass? Nor indeed is it, strictly speaking, a part of our ancient law: for the Mirror, having observed the necessity of counsel in civil suits, "who know how to forward and defend the cause by the rules of law and customs of the realm;" immediately afterwards subjoins, "and more necessary are they for defence upon indictments and appeals of felony, than upon other venial causes." And, to say the truth, the judges themselves are so sensible of this defect in our modern practice, that they seldom scruple to allow a prisoner counsel to stand by him at the bar, and to instruct him what questions to ask, or even to ask questions for him, with regard to matters of fact; for as to matters of law arising on the trial, they are entitled to the assistance of counsel. But still this is a matter of too much importance to be left to the good pleasure of any judge, and is worthy the interpolation of the legislature; which has shown its inclination to indulge prisoners with this reasonable assistance, by enacting, in statute 7 W. III. c. 3. that persons indicted for such high-treason as works a corruption of the blood or misprision thereof, (except treason in counterfeiting the king's coins or seals), may make their

full defence by counsel, not exceeding two, to be named by the prisoner and assigned by the court or judge; and this indulgence, by statute 20 Geo. II. c. 30. is extended to parliamentary impeachments for high-treason, which were excepted in the former act.

When the evidence on both sides is closed, the jury cannot be discharged till they have given in their VERDICT. If they find the prisoner not guilty, he is then for ever quit and discharged of the accusation; except he be appealed of felony within the time limited by law. And upon such his acquittal, or discharge for want of prosecution, he shall be immediately set at large without payment of any fee to the goaler. But if the jury find him guilty, he is then said to be convicted of the crime whereof he stands indicted. See the article CONVICTION; and, subsequent thereto, the articles JUDGMENT, ATTAINDER, FORFEITURE, EXECUTION, also *Benefit of CLERGY, REPRIEVE, PARDON.*

TRIANDRIA (from *τρεῖς* "three," and *ἀνδρ* "a man or husband"), the name of the third class in Linnaeus's sexual system, consisting of plants with hermaphrodite flowers, which have three stamina or male organs.

TRIANGLE, in geometry, a figure of three sides and three angles.

TRIBE, in antiquity, a certain quantity, or number of persons, when a division was made of a city or people into quarters or districts.

TRIBRACHYS, in ancient poetry, a foot consisting of three syllables, and these all short; as, *melior*.

TRIBUNAL, in general, denotes the seat of a judge, called in our courts *bench*.

TRIBUNAL, among the ancient Romans, a magistrate chosen out of the commons, to protect them against the oppressions of the great, and to defend the liberty of the people against the attempts of the senate and consuls.

The tribunals of the people were first established in the year of Rome 259. The first design of the creation was to shelter the people from the cruelty of usurers, and to engage them to quit the Aventine mount, whither they had retired in displeasure.

Their number at first was but two; but the next year, under the consulate of A. Posthumus Aruncius and Cassius V. vellicus, there were three more added; and this number of five was afterwards increased by L. Trebonius to ten.

Military TRIBUNE, an officer in the Roman army, commanded in chief over a body of forces, particularly the division of a legion; much the same with our colonel, or the French *maitre de camp*.

TRIBUTARY, one who pays tribute to another, in order to live in peace with him or share in his protection.

TRIBUTE, a tax or impost which one prince or state is obliged to pay to another as a token of dependence, or in virtue of a treaty, and as a purchase of peace.

TRICEPS, in anatomy. See there, *Table of the Muscles*.

TRICHECUS, the walrus; a genus of quadrupeds, belonging to the order of bruta. The characters are these. Two great tusks in the upper jaw, point.

1. The rosmarinus, morfe, or sea-horse, has a round head; small mouth; very thick lips, covered above and below with pellicid bristles as thick as a straw; small fiery eyes; two small orifices instead of ears; short neck; body thick in the middle, tapering towards the tail; skin thick, wrinkled, with short brownish hairs thinly dispersed: legs short; five toes on each, all connected by webs, and small nails on each: the hind feet are very broad; each leg loosely articulated; the hind legs generally extended on a line with the body: the tail is very short; penis long: length of the animal, from nose to tail, sometimes eighteen feet, and ten or twelve round in the thickest part: the teeth have been sometimes found of the weight of 20 lb. each. Teeth of this size are only found on the coast of the Icy Sea, where the animals are seldom molested, and have time to attain their full growth.

They inhabit the coast of Spitzbergen, Nova Zembla, Hudson's Bay, and the gulph of St Laurence; and the Icy Sea, as far as Cape Tchuktshi. They are gregarious; in some places appearing in herds of hundreds. They are shy animals, and avoid places which are much haunted by mankind; but are very fierce. If wounded in the water, they attempt to sink the boat, either by rising under it, or by striking their great teeth into the sides; they roar very loud, and will follow the boat till it gets out of sight. Numbers of them are often seen sleeping on an island of ice; if awoke, they fling themselves with great impetuosity into the sea; at which time it is dangerous to approach the ice, lest they should tumble into the boat and overset it. They do not go upon the land till the coast is clear of ice. At particular times, they land in amazing numbers: the moment the first gets on shore, so as to lie dry, it will not stir till another comes and forces it forward by beating it with its great teeth; this is served in the same manner by the next; and so in succession till the whole is landed, continuing tumbling over one another, and forcing the foremost, for the sake of quiet, to remove further up. The method of killing them on the Magdalene isles, in the gulph of St Laurence, according to Mr Pennant, is thus: The hunters watch their landing; and as soon as they find a sufficient number for what they call a *cut*, they go on shore, each armed with a spear sharp on one side like a knife, with which they cut their throats. Great care must be taken not to stand in the way of those which attempt to get again to sea, which they do with great agility by tumbling headlong; for they would crush any body to death by their vast weight. They are killed for the sake of their oil, one walrus producing about half a tun. The knowledge of this chase is of great antiquity; Other the Norwegian, about the year 890, made a report of it to king Alfred, having, as he says, made the voyage beyond Norway, for the more commoditie of fishing of horse-whales, which have in their teeth bones of great price and excellency, whereof he brought some at his return unto the king. In fact, it was, in the northern world, in early times, the substitute to ivory, being very white and very hard. Their skins, Other says, were good to cut into cables. M. de Buffon says, he

has seen braces for coaches made of the skin, which were both strong and elastic.

They bring one, or at most two young at a time: they feed on sea herbs and fish; also on shells, which they dig out of the sand with their teeth: they are said also to make use of their teeth to ascend rocks or pieces of ice, fastening them to the cracks, and drawing their bodies up by that means. Besides mauling, they seem to have no other enemy than the white bear, with whom they have terrible combats; but generally come off victorious, by means of their great teeth.

2. The manatus, manati, or sea-cow. This animal, in nature, so nearly approaches the cetaceous tribe, that it scarce deserves the name of a biped: what are called feet are little more than pectoral fins; they serve only for swimming: they are never used to assist the animal in walking or landing; for it never goes ashore, nor ever attempts to climb the rocks, like the sea-horse and seal. It brings forth in the water, and like the whale, suckles its young in that element: like the whale, it has no voice; and like that animal, has an horizontal broad tail, without even the rudiments of hind feet. It inhabits the shores of Kamtschaika, those of the opposite coast of America, and of the intervening islands. It is found again on that of Mindanao, one of the Philippine islands, and on the coast of New Holland; on that of the isle of France, and on that of Senegal; on the Mosquito shore, in the river Oronoque, and the lakes formed by it; and lastly, in the river of Amazons; but in no other part of the Atlantic Ocean.

They live perpetually in the water, and frequent the edges of the shores; and in calm weather swim in great groves near the mouths of rivers: in the time of flood they come so near the land, that a person may stroke them with his hand: if hurt, they swim out to sea; but presently return again. They live in families, one near another; each consists of a male, a female, a half-grown young one, and a very small one. The females oblige the young to swim before them, while the other old ones surround and as it were guard them on all sides. The affection between the male and female is very great: for if the male is attacked, he will defend her to the utmost; and if she is killed, will follow her corpse to the very shore, and swim for some days near the place it has been landed at. They copulate in the spring, in the same manner as the human kind, especially in calm weather, towards the evening. The female swims gently about; the male pursues; till tired with wantoning she flings herself on her back, and admits his embraces. Steller thinks they go with young about a year: it is certain that they bring but one young at a time, which they suckle by two teats placed between the breasts. They are vastly voracious and gluttonous; and feed not only on the fuci that grow in the sea, but such as are hung on the edges of the shore. When they are filled, they fall asleep on their backs. During their meals, they are so intent on their food, that any one may go among them and choose which he likes best. Peter Martyr gives an instance of one that lived in a lake of Hispaniola for 25 years, and was so tame as to come to the edge of the shore on being called; and would even perform the part of a ferry, and carry several people at a time on its back to the opposite shore.—Their back and their

Tricheus. their sides are generally above water; and as their skin is filled with a species of loose peculiar to them, numbers of gulls are continually perching on their backs and picking out the insects.

They continue in the Kamtschatka and American seas the whole year; but in winter are very lean, so that you may count their ribs. They are taken by harpoons fastened to a strong cord; and after they are struck, it requires the united force of thirty men to draw them on shore. Sometimes when they are transfixed, they will lay hold of the rocks with their paws, and flick so fast as to leave the skin behind before they can be forced off. When a manati is struck, its companions swim to its assistance; some will attempt to overturn the boat by getting under it; others will press down the rope, in order to break it; and others will strike at the harpoon with their tails, with a view of getting it out, in which they often succeed. They have not any voice; but make a noise by hard breathing, like the snorting of a horse.

They are of an enormous size; some are 28 feet long, and 8000lb. in weight. Those of the West Indies and other hot climates do not exceed 1200lb. in weight, and few arrive at that size. Probably they are not suffered to live their full time in those countries, being perpetually persecuted by the Mosquito and other Indians, who are very dexterous in striking them. The head, in proportion to the bulk of the animal, is small, oblong, and almost square: the nostrils are filled with short bristles: the gape, or rictus, is small: the lips are double: near the junction of the two jaws the mouth is full of white tubular bristles, which serve the same use as the lamina in whales, to prevent the food running out with the water: the lips are also full of bristles, which serve instead of teeth to cut the strong roots of the sea-plants, which floating ashore are a sign of the vicinity of these animals. In the mouth are no teeth, only two flat white bones, one in each jaw; one above, another below, with undulated surfaces, which serve instead of grinders.

The eyes are extremely small, not larger than those of a sheep: the iris is black. The animal is destitute of ears, having only two orifices, so small that a quill will scarce enter them: the tongue is pointed, and but small: the neck is thick, and its junction with the head scarce distinguishable; and the last always hangs down: the circumference of the body near the shoulders is twelve feet, about the belly twenty, near the tail only four feet eight; the head thirty-one inches the neck near seven feet: and from these measurements may be collected the deformity of this animal. Near the shoulders are two feet, or rather fins, which are only two feet two inches long, and have neither fingers nor nails; beneath they are concave, and covered with hard bristles: the tail is thick, strong, and horizontal, ending in a stiff black fin, and like the substance of whalebone, and much split in the forepart; the end slightly divided. The females have, between the pectoral fins, two large round and fair breasts; and both sexes have the parts of generation, and the navel, perfectly resembling those of the human species: there is no doubt, Mr Pennant thinks, but all the fables concerning mermaids, mermen, and syrens, took their rise from an imperfect view of this animal.

The skin is very thick, black, and full of inequalities, like the bark of oak, and so hard as scarce to be cut with an ax, and has no hair on it: beneath the skin is a thick blubber, which tastes like oil of almonds. The flesh is coarser than beef, and will not soon putrify. The young ones taste like veal. The skin is used for shoes, and for covering the sides of boats.

TRICOCCEÆ, (*τρις* "three," and *κακκς* "a grain"), the name of the thirty-eighth order in Linnæus's Fragments of a Natural Method, consisting of plants with a single three-cornered capsule, having three cells, or internal divisions, each containing a single seed. See **BOTANY**, p. 1313.

TRIDENT, an attribute of Neptune, being a kind of sceptre which the painters and poets put into the hands of that god, in form of a spear or fork with three teeth; whence the word.

TRIENNIAL, an epithet applied chiefly to officers or employments which last for three years.

TRIENNIAL Elections. The utmost extent of time that the same parliament was allowed to sit, by the stat. 6 W. & M. c. 2. was three years; after the expiration of which, reckoning from the return of the first summons, the parliament was to have no longer continuance. But by the stat. 1 Geo. I. st. 2. c. 38. this term was prolonged to seven years.

TRIENS, in antiquity, a copper money of the value of one third of an *as*, which on one side bore a Janus's head, and on the other a water rat.

TRIERS, or **TREVES**. See **TREVES**.

TRIESTE, a sea-port town of Istria, seated on the gulph of Venice, and belonging to the house of Austria. It was formerly a free city, and is situated on the declivity of a rock, eight miles north of Capo d'Istria, and seventy-two miles north-east of Venice, E. Long. 14. 12. N. Lat. 46. 10.

TRIFOLIUM, **TREFOIL**; a genus of the decandria order, belonging to the diadelphia class of plants. There are 43 species; of which the most remarkable are, 1. The *melilotis officinalis*, or *melilot*, is a native of Britain, growing in corn-fields and by the waysides, but not common. The stalk is erect, firm, striated, branched, and two or three feet high: the leaves ternate, smooth, obtusely oval, and serrated: the flowers are small, yellow, pendulous, and grow in long close spikes at the tops of the branches: the pod is very short, turgid, transversely wrinkled, pendulous, and contains either one or two seeds. The plant has a very peculiar strong scent, and disagreeable bitter acid taste, but such, however, as is not displeasing to cattle. The flowers are sweet-scented. It has generally been esteemed emollient and digestive, and been used in fomentations and cataplasms, particularly in the plaster employed in dressing blisters; but is now laid aside, as its quality is found to be rather acid and irritating than emollient or resolvent. It communicates a most loathsome flavour to wheat and other grain, so as to render it unfit for making bread.

2. The *repens*, white creeping trefoil, or Dutch trefoil, is common in meadows and pastures. It is well known to be an excellent fodder for cattle; and the leaves are a good rustic hygrometer, as they are always relaxed and flaccid in dry weather, but erect in moist or rainy.

Triga
Trigonella.

3. The pratense, purple trefoil or clover, frequent in meadows and pastures. It affords a very plentiful fodder to horses and other cattle; but when they feed too greedily on the fresh herb, it blows them up in such a manner with wind, that unless they are speedily relieved, by tapping them in the belly or some other similar operation, they soon perish. In Ireland the poor people, in a scarcity of corn, make a kind of bread of the dried flowers of this and the preceding plant reduced to powder. They call the plant *chavibrooch*, and esteem the bread made of it to be very wholesome and nutritive.

TRIGA, in antiquity, denotes a kind of carr or chariot drawn by three horses; whence the name.

TRIGLA, in ichthyology, a genus of fishes, belonging to the order of thoraciceæ. The head is loricated with rough lines, and there are seven rays in the membranes of the gills. There are nine species; of which the principal are the gurnardus, or grey gurnard; the cuculus, or red gurnard; the lyra, or piper; and the bimudo, or sapphirine gurnard.

TRIGLYPHS, in architecture, a sort of ornaments, repeated at equal intervals, in the Doric frieze.

TRIGONELLA, FENUGREEK; a genus of the

decandria order, belonging to the diadelphica class of Trigonella plants. There are 10 species; of which the most remarkable is the *fœnum præticum*, or common fenugreek, whose seeds are used in medicine. Where this plant grows naturally is uncertain; but it is cultivated in the fields in the south of France, and in Germany, from whence great quantities of the seeds are annually imported here for use. It is also much cultivated in India. It is an annual plant, which rises with a hollow, branching, herbaceous stalk a foot and a half high, garnished with trifoliate leaves, placed alternately, whose lobes are oblong, oval, indented on their edges, and have broad furrowed footstalks. The flowers come out singly at each joint from the wings of the stalk; they are white, of the butterfly kind, and sit very close to the stalk: these are succeeded by long compressed pods, shaped somewhat like a broad sword, ending in long points, having a broad membrane on one edge, filled with square yellow seeds, indented on one side like a kidney. The whole plant has a very strong odour.

The chief use of fenugreek seeds is as an ingredient in cataplasms, fomentations, emollient glysters, and in powders for horses, &c.

TRIGONOMETRY,

Plane.

IS that part of geometry which teaches how to measure the sides and angles of triangles.

Trigonometry is either plane or spherical, according as the triangles are PLANE or SPHERICAL; of each whereof we shall treat in order.

PLANE TRIGONOMETRY.

PLANE TRIGONOMETRY, or that which teaches the mensuration of plane triangles, is commonly divided into *rectangular* and *oblique-angular*.

Of RECTANGULAR PLANE TRIGONOMETRY.

IF in any right-angled triangle, ABC, (Plate CCLXXXVII. fig. 1. n° 1.) the hypotenuse be made the radius, and with that a circle be described on the one end, A, as a centre; then it is plain that BC will be the sine of the angle BAC; and if with the same distance, and on the end B as a centre, a circle be described, it is plain that AC will be the sine of the angle ABC: therefore, in general, if the hypotenuse of a right-angled triangle be made the radius, the two legs will be the sines of their opposite angles.

Again, if in a right-angled triangle DEF (*ibid.* n° 2.) one of the legs, as DF, be made the radius, and on the extremity D (at one of the oblique angles, *viz.* that which is formed by the hypotenuse and the leg made radius) as a centre, a circle be described; it is plain that the other leg, EF, will be the tangent of the angle at D, and the hypotenuse DE will be the secant of the same angle. The same way, making the leg EF the radius, and on the centre E describing a circle, the other leg DF will become the tangent of the angle at E, and the hypotenuse DE the secant of the same.

The chord, sine, tangent, &c. of any arch or angle, in one circle, is proportionable to the chord, sine, tangent, &c. of the same arch in any other circle: from which, and what has been said above, the solutions of

the several cases of rectangular trigonometry naturally follow.

Since trigonometry consists in determining angles and sides from others given, there arise various cases; which being seven in rectangular trigonometry, are as follow.

CASE I. The angles, and one of the legs, of a right-angled triangle being given, to find the other leg.

EXAMPLE. In the triangle ABC (*ibid.* n° 3.) right-angled at B, suppose the leg AB=86 equal parts, as feet, yards, miles, &c. and the angle A=33° 40'; required the other leg BC, in the same parts with AB.

I. *Geometrically.* Draw AB=86, from any line of equal parts; upon the point B, erect the perpendicular BC; and, lastly, from the point A, draw the line AC, making with AB an angle of 33° 40'; and that line produced will meet BC in C, and so constitute the triangle. The length of BC may be found by taking it in your compasses, and applying it to the same line of equal parts that AB was taken from.

II. *By calculation.* First, by making the hypotenuse AC radius, the other two legs will be the sines of their opposite angles, *viz.* AB the sine of C, and CB the sine of A. Now since the sine, tangent, &c. of any arch in one circle is proportionable to the sine, tangent, &c. of the same arch in any other circle, it is plain the sines of the angles A and C in the circle described by the radius AC, must be proportional to the sine of the same arches or angles, in the circle, that the table of artificial lines, &c. was calculated for; so the proportion for finding BC will be

$$S, C : AB :: S, A : BC.$$

i. e. as the sine of the angle C in the tables is to the length of AB (or sine of C in the circle whose radius is AC), so is the sine of the Angle A in the tables, to the length of BC (or sine of the same angle in the circle whose radius is AC). Now the angle A being 33° 40', the angle C must be 56° 20'; therefore looking in the

Plane. table of artificial fines, &c. for the fines of the two angles, and in the table of logarithms for the logarithm of 86 the given leg, we shall find, by proceeding according to the foregoing proportion, that the required leg, BC, is 57.28; and the operation will stand as follows:

$$\begin{array}{l} 1.93450 \text{ AB } 86 \\ 9.74380 \text{ S, A } 33^\circ 40' \end{array}$$

$$\begin{array}{l} 11.67830 \\ 9.92027 \text{ S, C } 56^\circ 20' \end{array}$$

$$1.75803 \text{ BC } 57.28$$

Secondly, making AB the radius, it is plain BC, the leg required, will be the tangent of the given angle A; and so the proportion for finding BC, when AB is made the radius, will be:

$$R : T, A :: AB : BC.$$

i. e. as the radius in the tables is to the tangent of the angle A in the same; so the length of BA, or radius in the scheme, to the length of BC or tangent of A in the scheme: therefore looking in the tables for the parts given in the foregoing proportion, and proceeding with them according to that rule, we shall find BC to be 57.28 as before, and the operation will be as follows:

$$\begin{array}{l} 9.82352 \text{ T, A } 33^\circ 40' \\ 1.93450 \text{ AB } 86 \end{array}$$

$$\begin{array}{l} 11.75802 \\ 10.00000 \text{ Rad. } 90^\circ \end{array}$$

$$175802 \text{ BC } 57.28$$

Lastly, by making BC, the leg required, the radius, it is plain that AB will be the tangent of C; and the proportion for finding BC will be as follows:

$$T, C : R :: AB : BC.$$

i. e. as the tangent of C $56^\circ 20'$ 10.17648
is to radius 90° 10.00000
so is the length of AB 86 1.93450

$$\begin{array}{l} 11.93450 \\ 10.17648 \end{array}$$

to the length of BC 57.28 1.75802

CASE II. The angles and one of the legs given, to find the hypotenuse.

EXAMPLE: In the triangle ABC, (*ibid.* n° 4.) suppose AB 124, and the angle A $34^\circ 20'$; consequently the angle C $55^\circ 40'$, required the hypotenuse AC, in the same parts with AB.

I. *Geometrically*: This case is constructed after the same manner with the former; and the hypotenuse, AC, is found by taking its length in your compasses, and applying that to the same line of equal parts from which AB was taken.

II. *By calculation*: First, making AC the radius, we shall have the following proportion for finding AC, viz.

$$S, C : R :: AB : AC.$$

i. e. As the sine of C $55^\circ 40'$ 9.91686
is to radius 90° 10.00000
so is AB 124 2.09342
to AC 150.2 2.17656

Secondly, making AB the radius, we have this proportion, viz.

R : sec. A :: AB : AC.
i. e. as the radius 90° 10.00000
as the secant of A $34^\circ 20'$ 10.08314
so is AB 124 2.09342
to AC 150.2 2.17656

This may also be done without the help of the secants: for since R : sec. :: Co-S. : R; therefore the former proportion will become,

$$\text{Co-S, A : R :: AB : AC.}$$

i. e. as the co-sine of A $34^\circ 20'$ 9.91686
is to the radius 90° 10.00000
so is AB 124 2.09342
to AC 150.2 2.17656

Thirdly, making BC the radius, we have the following proportion, viz.

$$T, C : \text{sec. C} :: AB : AC.$$

i. e. as the tangent of C $55^\circ 40'$ 10.16558
is to sec. C $55^\circ 40'$ 10.24872
so is AB 124 2.09342
to AC 150.2 2.17656

This likewise may be done without the help of secants; for since T : Sec. :: S : R; therefore the former analogy will be reduced to this, viz.

$$S, C : R :: AB : AC.$$

where no secants do appear; and it coincides with that in the first supposition of this case, so we shall not repeat the operation.

CASE III. The angles and hypotenuse given, to find either of the legs.

EXAMPLE. In the triangle ABC, (*ibid.* n° 4.) suppose the hypotenuse AC=146, and the angle A= $36^\circ 25'$; consequently the angle C= $53^\circ 35'$; required the leg, AB.

I. *Geometrically*: Draw the line AB at pleasure, and make the angle BAC equal to $36^\circ 25'$; then take AC equal to 146 from any line of equal parts; lastly, from the point C, let fall the perpendicular CB, on the line AB. So the triangle is constructed, and AB may be measured from the line of equal parts.

II. *By calculation*: First, making AC the radius, we shall have the following proportion, viz.

$$R : S, C :: AC : AB.$$

i. e. as radius 90° 10.00000
to the sine of C $53^\circ 35'$ 9.90565
so is AC 146 2.16435
to AB 117.5 2.07000

Secondly, making AB the radius, we have the following analogy, viz.

$$\text{Sec. A : R :: AC : AB.}$$

i. e. as the secant of A $36^\circ 25'$ 10.09435
is to radius 90° 10.00000
so is AC 146 2.16435
to AB 117.5 2.07000

This may also be done without the help of secants; for since sec. : R :: R : Co-S, the former proportion may be reduced to this, viz.

$$R : \text{Co-S, A} :: AC : AB,$$

which is the same with the proportion in the first supposition.

Thirdly, by supposing BC the radius, we have the following proportion, viz.

$$\text{Sec. C : T, C} :: AC : AB,$$

i. e. as the secant of C $53^\circ 35'$ 10.22647
is to the tangent of C $53^\circ 35'$ 10.13214
so is AC 146 2.16435
to AB 117.5 2.07000

CASE

Plane.

CASE IV. The two legs being given, to find the angles.

EXAMPLE. In the triangle ABC, (*ibid.* n° 5.) suppose AB 94, and BC 56, required the angles A and C.

I. *Geometrically*: Draw AB equal to 94, from any line of equal parts; then from the point B raise BC perpendicular to AB, and take BC from the former line of equal parts equal to 56; lastly, join the points A and C with the straight line AC: so the triangle is constructed, and the angles may be measured by a line of chords.

II. *By calculation*: First, supposing AB the radius, we have this analogy, *viz.*

$$AB : BC :: R : T, A.$$

| | | |
|---------------------|---------|----------|
| i. e. as AB | 94 | 1.97313 |
| is to BC | 56 | 1.74819 |
| so is the radius | 90° | 10.00000 |
| to the tangent of A | 30° 47' | 9.77506 |

Secondly, making BC the radius, we have this proportion, *viz.*

$$BC : BA :: RT, B.$$

| | | |
|---------------------|---------|----------|
| i. e. as BC | 56 | 1.74819 |
| is to AB | 94 | 1.97313 |
| so is the radius | 90° | 10.00000 |
| to the tangent of C | 59° 13' | 10.22494 |

CASE V. The hypotenuse and one of the legs given, to find the angles.

EXAMPLE. In the triangle DEF, (*ibid.* n° 6.) suppose the leg DE=83, and the hypotenuse DF=126; required the angles D and F.

I. *Geometrically*: Draw the line DE=83 from any line of equal parts; and from the point E raise the perpendicular EF: then take the length of DF=126, from the same line of equal parts; and setting one foot of your compasses in D, with the other cross the perpendicular EF in E; lastly, join D and F, and the triangle being thus constructed, the angles may be measured by a line of chords.

II. *By calculation*: First, making DF the radius, we shall have this proportion, *viz.*

$$DF : DE :: R : S, F.$$

| | | |
|------------------|---------|----------|
| i. e. as DF | 126 | 2.10037 |
| is to DE | 83 | 1.91908 |
| so is radius | 90° | 10.00000 |
| to the sine of F | 41° 12' | 9.81871 |

Secondly, by supposing DE the radius, we have the following analogy, *viz.*

$$DE : DF :: R : \text{Sec. D.}$$

| | | |
|--------------------|---------|----------|
| i. e. as DE | 83 | 1.91908 |
| is to DF | 126 | 2.10037 |
| so is radius | 90° | 10.00000 |
| to the secant of D | 48° 48' | 10.18129 |

This may be done without the help of secants; for since R : sec. :: Co-S, : R, the foregoing analogy will become this, *viz.*

$$DF : DE :: R : \text{Co-S, D.}$$

which gives the same answer with that deduced from the first supposition.

CASE VI. The two legs being given, to find the hypotenuse.

EXAMPLE. In the triangle ABD, (*ibid.* n° 7.) suppose the leg AB=64, and BD=56: required the hypotenuse.

I. *Geometrically*: The construction of this case is performed the same way as in the fourth case; and the length of the hypotenuse is found by taking it in your

compasses, and applying it to the same line of equal parts that the two legs were taken from.

II. *By calculation*: This case being a compound of the fourth and second cases, we must first find the angles by the fourth, thus:

$$AB : DB :: R : T, A.$$

| | | |
|---------------------|---------|----------|
| i. e. as the leg AB | 64 | 1.80618 |
| is to the leg DB | 56 | 1.74819 |
| so is the radius | 90 | 10.00000 |
| to the tangent of A | 41° 11' | 9.54201 |

Then by the second case we find the hypotenuse required, thus:

$$S, A : R :: BD : AD.$$

| | | |
|------------------------|---------|----------|
| i. e. as the sine of A | 41° 11' | 9.81854 |
| is to the radius | 90° | 10.00000 |
| so is the leg BD | 56 | 1.74819 |
| to the hypoth. AD | 85.05 | 1.92965 |

This case may also be solved after the following manner, *viz.*

From twice the logarithm of the greater

$$\text{side AB} \quad 3.61236$$

$$\text{subtract the logarithm of the lesser side BD} \quad 1.74819$$

$$\text{and there remains} \quad 1.86417$$

the logarithm of 73.15; to which adding the lesser side BD, we shall have 189.15, whose logarithm is 2.11093

$$\text{to which add the logarithm of the lesser side BD} \quad 1.74819$$

$$\text{and the sum will be} \quad 3.85912$$

$$\text{the half of which is} \quad 1.92956$$

the logarithm of the hypotenuse required.
Or it may be done by adding the square of the two sides together, and taking the logarithm of that sum, the half of which is the logarithm of the hypotenuse required: thus, in the present case, the square of AB (64) is 4096 the square of BD (56) is 3136

the sum of these squares is 7232 the logarithm of which is 3.85926 the half of which is 1.92962= to the logarithm of 85.05, the length of the hypotenuse required.

CASE VII. The hypotenuse and one of the legs being given, to find the other leg.

EXAMPLE. In the triangle BGD, (*ibid.* n° 8.) suppose the leg BG=87, and the hypotenuse BD=142; required the leg DG.

I. *Geometrically*: The construction here is the same as in case V. the same things being given; and the leg DG is found by taking its length in your compasses, and applying that to the same line of equal parts the others were taken from.

II. *By calculation*: The solution of the case depends upon the 1st and 5th; and first we must find the oblique angles by case 5th, thus:

$$BD : BG :: R : S, D.$$

| | | |
|-------------------------|---------|----------|
| i. e. as the hypoth. DB | 142 | 2.15229 |
| is to the leg BG | 87 | 1.93952 |
| so is radius | 90° | 10.00000 |
| to the sine of D | 37° 47' | 97.8723 |

Then, by case 1st, we find the leg DG required, thus:

$$R : S, B :: BD : DG.$$

| | | |
|-----------------|--------|----------|
| i. e. as radius | 90° | 10.00000 |
| | 43 L 2 | 18 |

Plane. is to the sine of B $52^{\circ} 13'$ 9.89781
 so is the hypoth. DB 142 2.15229
 to the leg DG 112.2 2.05010

The leg DG may also be found in the following manner, viz.

To the log. of the sum of the hypotenuse } 2.35984
 and given leg. viz. 229 - - - }
 add the logarithm of their difference, viz. 55 1.74036

and their sum 4.10020
 the half of that is 2.05010

the log. of 112.2 the leg required

Or it may be done by taking the square of the given leg from the square of the hypotenuse, and the square root of the remainder is the leg required: thus, in the present case,

The square of the hypotenuse (142) is 20164
 The square of the leg BG (87) is 7569

Their difference is 12595
 Whose logarithm is 4.10020
 The half of which is 2.05010

which answers to the natural number 112.2, the leg required.

Thus we have gone through the seven cases of right-angled plane trigonometry; from which we may observe, 1. That to find a side, when the angles are given, any side may be made the radius. 2. To find an angle, one of the given sides must of necessity be made the radius.

OF OBLIQUE-ANGLED PLANE TRIGONOMETRY.

In oblique-angled plane trigonometry there are six cases; but before we show their solution, it will be proper to premise the following theorems.

THEOREM I. In any triangle ABC, (*ibid.* fig. 2. n° 2.) the sides are proportional to the sines of the opposite angles: thus, in the triangle ABC, AB : BC :: S : C, S, A, and AB : AC :: S, C : S, B : also AC : BC :: S, B : S, A.

Demonstration. Let the triangle ABC be inscribed in a circle; then it is plain (from the property of the circle) that the half of each side is the sine of its opposite angle: but the sines of these angles, in tabular parts, are proportional to the sines of the same in any other measure; therefore, in the triangle ABC, the sines of the angles will be as the halves of their opposite sides; and since the halves are as the wholes, it follows, that the sines of the angles are as their opposite sides; i. e. S, C : S, A :: AB : BC, &c.

THEOR. II. In any plane triangle, as ABC, (*ibid.* n° 2.) the sum of the sides AB and BC, is to the difference of these sides, as the tangent of half the sum of the angles BAC, ABC, at the base, is to the tangent of half the difference of these angles.

Demon. Produce AB; and make BH equal to BC; join HC, and let BD fall the perpendicular BE; through B draw BD parallel to AC, and make HF equal to CD, and join BF; also take BI equal to BA, and draw IG parallel to BD or AC.

Then it is plain that AH will be the sum, and HI the difference of the sides AB and BC; and since HB is equal to BC, and BE perpendicular to HC, therefore HE is equal to EC; and BD being parallel to AC and IG, and AB equal to BI, therefore CD or HF is equal to GD, and consequently HG is equal to

FD, and half HG is equal to half FD or ED. Again, since HB is equal to BC, and BE perpendicular to HC, therefore the angle EBC is half the angle HBC; but the angle HBC is equal to the sum of the angles A and C, consequently the angle EBC is equal to half the sum of the angles A and C. Also, since HB is equal to BC, and HF equal to CD, and the included angles BHF BCD equal, it follows that the angle HBF is equal to the angle DBC, which is equal to BCA; and since HBD is equal to the angle A, and HBF equal to BCA, therefore FBD is the difference, and EBD half the difference of the two angles A and BCA: so making EB the radius, it is plain EC is the tangent of half the sum, and ED the tangent of half the difference of the two angles at the base. Now IG being parallel to AC, the triangles HIG and HAC will be equiangular; consequently AH : IH :: CH : GH; but the wholes are as their halves, therefore AH : IH :: $\frac{1}{2}$ CH : $\frac{1}{2}$ GH; and since $\frac{1}{2}$ CH is equal to EC, and $\frac{1}{2}$ GH equal to $\frac{1}{2}$ FD=ED, therefore AH : IH :: EC : ED. Now AH is the sum and IH the difference of the sides; also EC is the tangent of half the sum, and ED the tangent of half the difference of the two angles at the base; consequently, in any triangle, as the sum of the sides is to their difference, so is the tangent of half the sum of the angles at the base to the tangent of half their difference.

THEOREM III. If to half the sum of two quantities be added half their difference, the sum will be the greater of them; and if from half their sum be subtracted half their difference, the remainder will be the least of them. Suppose the greater quantity to be $x=8$, and the lesser $z=6$; then is their sum 14, and difference 2:

wherefore, adding $\frac{14}{2}=7$ to $\frac{2}{2}=1$, we

get 8 the greatest of the two quantities:

and, in the same manner, $\frac{14}{2}-\frac{2}{2}=7-1=$

6 , the least of the two quantities.

THEOREM IV. In any right-lined triangle, ABD (*ibid.* n° 3.) the base AD is to the sum of the sides AB and BD, as the difference of the sides is to the difference of the segments of the base made by the perpendicular BE, viz. the difference between AE and ED.

Demon. Produce DB till BG be equal to BA the lesser leg; and on B as a centre, with the distance BA or BG, describe the circle AGHF, which will cut BD and AD in the points H and F: then it is plain GD is the sum, and HD the difference of the sides; also since AD is equal to EF, therefore FD is the difference of the segments of the base; but AD : GD :: HD : FD; therefore the base is to the sum of the sides, &c. as was to be proved.

Having established these preliminary theorems, we shall now proceed to the solution of the six cases of oblique-angled plane trigonometry.

CASE I. In any oblique-angled plane triangle, two sides and an angle opposite to one of them being given, to find the angle opposite to the other.

EXAMPLE. In the triangle ABC, (*ibid.* n° 4.) suppose AB=16, BC=84, and the angle C (opposite to AB)= $56^{\circ} 30'$; required the angle A, opposite to BC.

Plane.

Plane.

2. *Geometrically*: Draw the line AC, and at any point of it, suppose C, make the angle $C=60^\circ 30'$; then take $CB=84$, and with the length of $156=AB$ taken in your compasses from the same scale of equal parts, fixing one point in B, with the other cross AC in A. Lastly, join A and B; so the triangle is constructed, and the required angle A may be measured by a line of chords.

2. *By calculation*: We have, by theor. 1. the following proportion for finding the angle A, viz.

$$AB : BC :: S, C : S, A.$$

| | | |
|-------------|----------------|---------|
| i. e. as AB | 156 | 2.19312 |
| to BC | 84 | 1.92428 |
| so is S, C | $56^\circ 30'$ | 9.92111 |
| to S, A | $26^\circ 41'$ | 9.65227 |

CASE II. The angles, and a side opposite to one of them, being given, to find a side opposite to another.

EXAMPLE. In the triangle HBG (*ibid.* n° 5.) suppose the angle H $46^\circ 15'$, and the angle B $54^\circ 22'$, consequently the angle G $79^\circ 23'$, and the leg HB 125, required HG.

Geometrically: Draw HB 125, from any line of equal parts, and make the angle H $46^\circ 15'$, and B $54^\circ 22'$, then produce the lines HG and BG till they meet one another in the point G: so the triangle is constructed, and HG is measured by taking its length in your compasses, and applying it to the same line of equal parts that HB was taken from.

2. *By calculation*: By the first of the preceding theorems, we have this analogy for finding HG, viz.

$$S, G : HB :: S, B : HG.$$

| | | |
|------------------------|----------------|---------|
| i. e. as the sine of G | $79^\circ 23'$ | 9.99250 |
| is to the leg HB | 125 | 2.09691 |
| so is the sine of B | $54^\circ 22'$ | 9.90996 |
| to the leg HG | 103.4 | 2.01437 |

CASE III. Two sides and an angle opposite to one of them given, to find the third side.

EXAMPLE. In the triangle KLM (*ibid.* n° 6.) suppose the side CL 126 equal parts, and KM 130 of these parts, and the angle L (opposite to KM) $63^\circ 20'$, required the side ML.

1. *Geometrically*: The construction of this case is the same with that in Case I. (there being the same things given in both), and the leg ML may be measured by applying it to the same line of equal parts that the other two were taken from.

2. *By calculation*: The solution of this case depends upon the two preceding ones; and, first, we must find the other two angles by Case I. thus:

$$MK : S, L :: KL : S, M.$$

| | | |
|----------------------|----------------|---------|
| i. e. as the side MK | 130 | 2.11394 |
| to the sine of L | $63^\circ 20'$ | 9.95116 |
| so is the side KL | 126 | 2.10037 |
| to the sine of M | $60^\circ 1'$ | 9.93759 |

Then by Case II. we have the required leg ML, thus:

$$S, L : S, K :: MK : ML.$$

| | | |
|------------------------|----------------|---------|
| i. e. as the sine of L | $63^\circ 20'$ | 9.95116 |
| to the sine of K | $53^\circ 39'$ | 9.90602 |
| so is KM | 130 | 2.11394 |
| to ML | 117.2 | 2.06850 |

CASE IV. Two sides and the contained angle being given, to find the other two angles.

EXAMPLE. In the triangle ACD (*ibid.* n° 7.) suppose AC=103, AD=126, and the angle A= $54^\circ 30'$; required the angles C and D.

1. *Geometrically*: Draw AD=126, and make the angle A= $54^\circ 30'$; then set off 103 equal parts from A to C: lastly, join C and D; and so the triangle is constructed, and the angles C and D may be measured by a line of chords.

2. *By calculation*: The solution of this case depends upon the second and third of the preceding theorems; and first we must find the sum and difference of the sides, and half the sum of the unknown angles, thus:

| | |
|---------------|-----|
| The leg AD is | 126 |
| The leg AC is | 103 |

| | |
|---------------------------------------------|----------------|
| Their sum is | 229 |
| And their difference is | 23 |
| The sum of the three angles A, D, and C, is | 180° |
| The angle A is | $54^\circ 30'$ |

So the sum of the angles C and D will be $125^\circ 30'$
And half their sum is $62^\circ 45'$

Then by theor. 2. we have the following proportion, viz.

| | |
|---------------------------------------|---------|
| As the sum of the sides AD and AC=229 | 2.35984 |
| To their difference | 23 |

So is the tangent of half the sum of the unknown angles C and D. } $62^\circ 45'$ 10.28816

To tang. of half their difference } $11^\circ 2'$ 9.29005

Now having half the sum and half the difference of the two unknown angles C and D, we find the quantity of each of them by theorem 3. thus:

| | |
|---------------------------------------------|----------------|
| To half the sum of the angles C and D, viz. | $62^\circ 45'$ |
| Add half their difference, viz. | $11^\circ 02'$ |

And the sum of the greater angle C } $73^\circ 47'$

Again from half their sum, viz. } $62^\circ 45'$
Take half their difference, viz. } $11^\circ 02'$

And there will remain the lesser angle D } $=51^\circ 43'$

N. B. The greater angle is always that subtended by the greater side: thus, in the present case, the greater angle C is subtended by the greater side AD; and the lesser angle D is subtended by the lesser side AC.

CASE V. Two sides and the contained angle being given, to find the third side.

EXAMPLE. In the triangle BCD (*ibid.* n° 8.) suppose BC=154, BD=133, and the angle B= $56^\circ 03'$; required the side CD.

1. *Geometrically*: The construction of the case is the same with that of the last, and the length of DC is found by taking its length in your compasses, and applying it to the same line of equal parts that the two legs were taken from.

2. *By calculation*: The solution of this case depends upon the second and fourth; and first we must find the angles by the last case; thus:

| | |
|---------------------------------------|---------|
| As the sum of the sides BD and BC 287 | 2.45788 |
| Is to their difference 21 | 1.32222 |

So is the tangent of half the sum of the angles D and C } $61^\circ 58'$ 10.27372

To the tangent of half their difference $7^\circ 50'$ 9.13806

So by theorem 3. we have the angles D and C thus:
To half the sum of the angles D and C } $61^\circ 58'$
Add half their difference } $7^\circ 50'$

And

| | | | | |
|--------|------------------------------------|---------|-----------------------------------------|---------|
| Plane. | And the sum is the greater angle D | 69° 48' | The sum of all the three angles is 180° | |
| | Also, from half the sum | 61° 58' | The sum of A and C is | 83° 10' |
| | Take half the difference | 7° 50' | | |

And there remains the lesser angle C 54° 08'
Then by Case II. we have the following analogy for finding DC, the leg required, viz.

| | |
|-------------------------|-----------------|
| S, C : BD :: S, B : DC. | |
| i. e. as the sine of C | 54° 08' 9.90869 |
| to BD | 133 2.12385 |
| so is the sine of B | 56° 03' 9.91883 |
| to DC | 136.2 2.13399 |

CASE VI. Three sides being given, to find the angles.

EXAMPLE. In the triangle ABC, (*ibid.* n° 9.) suppose AB=156, AC=185.7, and BC=84; required the angles A, B, and C.

I. *Geometrically*: Make AC=185.7 from any line of equal parts; and from the same line taking 156=AB in your compasses, fix one foot of them in A, and with another sweep an arch; then take 84=BC in your compasses, and fixing one foot in C, with the other sweep an arch, which will cross the former in B: lastly, join the points B and A, and B and C; so the triangle will be constructed, and the angles may be measured by a line of chords.

II. *By calculation*: Let fall the perpendicular, BD, from the vertex B, upon the base AC; which will divide the base into two segments AD and DC, the lengths whereof may be found by theorem 4. thus:

| | | |
|-----------------------------------|-------|---------|
| As the base AC | 185.7 | 2.26893 |
| To the sum of the sides AB and BC | 240 | 2.38031 |
| So is the difference of the sides | 72 | 1.85733 |

To the diff. of the segments of the base 93 1.96871

And having the sum of the segments, viz. the whole base, and their difference, we find the segments themselves, by theorem 3. thus:

| | |
|---------------------------------|------|
| To half the sum of the segments | 92.8 |
| And half their difference | 46.5 |

| | |
|---------------------------------------|-------|
| And the sum is the greater segment AD | 139.3 |
| Also from half the sum of the segment | 92.8 |
| Take half their difference | 46.5 |

The remainder is the lesser segment DC 46.3

Now the triangle ABC is divided, by the perpendicular BD, into two right-angled triangles, ADB and DBC; in the first of which are given the hypotenuse AB=156, and the base AD=139.3, to find the oblique angle, for which we have (by Case V. of rectangular trigonometry) the following analogy, viz.

| | | |
|------------------|-------|----------|
| as AB | 156 | 2.19312 |
| to AD | 139.3 | 2.14395 |
| so is the radius | 90° | 10.00000 |

to the co-sine of the angle A 26° 40' 9.95083

Also the angle C is found by the same case, thus:

| | | |
|------------------|------|----------|
| as BC | 84 | 1.92428 |
| to CD | 46.3 | 1.66558 |
| so is the radius | 90° | 10.00000 |

to the co-sine of C 56° 30' 9.74130

Having found the two angles A and C, we have the third, B, by taking the sum of the other two from 180, thus:

The angle B is 96° 50'

All the proportions used for the solutions of the several cases in plane trigonometry may be performed by the scale and compass. On the scale there are several logarithmic lines, viz. one of numbers, another of sines, and one of tangents, &c.

And the way of working a proportion by these is this, viz. extend your compasses from the first term of your proportion, found on the scale, to the second; and with that extent, fixing one foot in the third term, the other will reach the fourth term required.

SPHERICAL TRIGONOMETRY.

SPHERICAL TRIGONOMETRY is the art whereby, from three given parts of a spherical triangle, we discover the rest; and, like plane trigonometry, is either right-angled or oblique angled. But before we give the analogies for the solution of the several cases in either, it will be proper to premise the following theorems:

THEOREM I. In all right-angled spherical triangles, the sign of the hypotenuse : radius :: sine of a leg : sine of its opposite angle. And the sine of a leg : radius :: tangent of the other leg : tangent of its opposite angle.
